There has been very little change except that the cheap offerings, referred to last week, seem to have stopped; this has caused a steadier market. There have been further sales of spot, New York, up to 9.37½c. The quotation of the American Smelting & Refining Co. continues unchanged at 9c., St. Louis, or 9.25c., New York, while that of the outside market for early delivery is 8.40c., St. Louis, or 8.75c., New York. Shipments from the West are still more or less tied up because of strikes, and all sales made are subject to strikes and embargoes.

ANTIMONY

There is very little interest in the market and prices for ordinary grades are around 10 to 10.25c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

The virgin metal, 98 to 99% pure, can be bought at 33c., New York, from the leading interests or at 31.50c., New York, from independent sellers in wholesale lots for early delivery.

ORES

Tungsten: There has been no change and prices are largely nominal but firm at \$7 to \$15 per unit in 60% concentrate. The market is still awaiting the tariff settlement.

Ferro-tungsten and tungsten powder are quoted at 85c. to \$1.15 per lb. of contained tungsten. British and French alloy is being freely offered, but some of it contains copper, which is unacceptable to certain consumers.

Molybdenum: The market is inactive and prices are unchanged at around 75c. per lb. of MoS₂ in 90% concentrate.

Manganese: No sales are recorded, but quotations appear to be unchanged at 65 to 80c. per unit, seaboard, for high-grade foreign ore, depending on delivery. Imports in March are reported as 18,970 tons, bringing the total for the nine months ended April 1 to 151,098 tons as compared with 431,718 tons for the same nine months in 1919.

Manganese-Iron Alloys: Ferro-manganese is quiet with a fair inquiry for delivery before July 1, but little for the last half. Quotations are unchanged and firm at \$200, delivered, for the last half and \$250, delivered, for early delivery of domestic alloy. A little British alloy can be bought at \$195, seaboard, for last half and at \$225 to \$250 for delivery before July 1. Spiegeleisen is quiet but strong at \$75, furnace, with domestic sales up to 600 tons recorded. There is a moderate foreign inquiry, which the high prices may hinder from developing into business.

Imports of ferro-manganese in March were 2860 tons, making the total for the nine months ended March 31, 26,280 tons as against 17,905 tons for the same nine months in 1919.

*Of this sum \$1,652,260 was paid by the individual companies prior to their amalgamation in 1914.

*This is a capital distribution, and reduces the par value of the stock from \$5 to \$4, corresponding to a reduction in total capitalization from \$3,000,000 to \$2,400,000.

Company Reports

RAY CONSOLIDATED COPPER CO.

Report for the year ended December 31, 1919.

Property: mine, mill, and railway at Ray, Arizona.

Operating Officials: L. S. Cates, general manager; W. S. Boyd, manager; C. A. Smith, superintendent of mines; D. D. Moffat, superintendent of mills.

Financial Statement: operating revenue from copper, gold, and silver sold, \$8,252,505; operating expense, \$7,185,986. Net income from operations plus depletion, \$1,066,519. Miscellaneous income, \$300,124. Balance on December 31, 1919, \$14,929,732.

Dividends: during 1919 \$3,154,358; total to date, \$23,835,441.

Development: owing to curtailment of production during the year, development was also limited, the total for the year consisting of 31,979 ft., as compared with 61,711 ft. for the year 1918. At No. 1 shaft 11,275 ft. was driven as compared with 26,576 ft. for the previous year; at No. 2 shaft, 19,328 ft. as compared with 34,293 ft.; at No. 3 shaft, 476 ft. as compared with 548 ft. The total development since the beginning of operations to the end of the year 1919 was 742,953 ft., or approximately 140.5 miles. Mining operations to the same date have destroyed 397,954 ft., and there remains intact 344,139 ft., or approximately 65 miles. The total ore-reserves on December 31, 1919, were 84,736,384 tons, averaging 2.963% copper. These reserves were not recalculated at the end of the year but were obtained by deducting the tonnage mined during the year from the ore-reserves reported at the end of the previous year.

Production: the total ore milled for the year was 1,621,600 dry tons, corresponding to a daily average of 4443 tons, as compared with 3,411,000 dry tons during 1918. The

average grade of the ore milled for 1919 was 1.814% copper as compared with 1.613% for 1918. The average recovery was 79.45% of the entire copper content, equivalent to 28.83 lb. of copper per ton. The gross production of copper was 46,746,893 lb. in concentrates, and 724,429 lb. in smelting ore.

CONSOLIDATED INTERSTATE-CALLAHAN MINING CO.

Report for the year ended December 31, 1919.

Property: mine and mill in the Coeur d'Alene district.

Operating Officials: C. W. Newton, mine manager; D. F. Haley, consulting engineer.

Financial Statement: income from 4 1/2 months production, \$487,303; miscellaneous income, \$6960; proceeds from sale of stocks and bonds, \$478,401; total, \$972,665. Cost of mining and royalties, \$447,929; general expense, \$51,579; improvements and maintenance, \$103,394. Surplus for the year, \$369,763.

Dividends: none during 1919; total to date, \$6,966,082.

Development: during the period from March 1 to October 15, while mining and shipping operations were suspended, the company carried on extensive development work, with the result that the most important discovery on the Interstate-Callahan in recent times was made. Ore was found in a cross-cut north of the 500-ft. level, which consists of a large body of high-grade, assaying as high as 34% lead, 31% zinc, and 7 oz. of silver per ton. The new orebody is identical with the big vein that has made the mine one of the largest producers of zinc-lead in the United States. The orebody has widened out with further development from 2 ft. to 321 feet.

Production: 67,952 tons of ore was mined and 52,526 tons was milled with an average content of 2.57 oz. silver, 7.73% lead, and 17.17% zinc.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

'YDRANGE' PUMPS

After a pump has been installed it frequently happens that a change in conditions makes it desirable to have a pump of greater capacity or for greater working lift, and it is with such conditions in view that the Aldrich Pump Co. has developed the 'ydrange' type of machine. The accompanying illustration shows a vertical triplex pump of this kind directly geared through a flexible coupling to an electric motor. Following are the outstanding features of this style of pump

1. The valves are arranged to work satisfactorily at a

Aldrich 'Ydrange' Triplex Pump

high pump-speed as well as at a normal speed so that the pump can be started at a normal speed and increased as the water requirements demand.

2. The working parts are made proportionally heavy so that the working head or pressure can be increased considerably over normal pressure.

3. The working barrel of the pump is so constructed that different sizes of plungers can readily be employed for changes in working pressure.

4. An arrangement of lubrication is so employed that all working parts can be completely oiled while the pump is in operation.

The fact that the speed, size of plungers, capacity, and working pressure can be easily altered, makes this type of

machine of more than ordinary value. The pump is sectional, having its standards, main journals, plunger guides, cross-heads, etc., separate, which facilitates handling. As many parts as possible are made alike and interchangeable, simplifying the matter of repair parts. This construction produces a very compact and simple machine, with accessibility of working parts always a prominent feature. These pumps are suitable for general pumping requirements as encountered about mills, mines, and quarries.

Proper operation is an important factor in getting the best results from any pumping equipment.

When the pump is first started, use plenty of oil on the bearings to wash out any dirt or dust, take up the lost motion on the connecting rods and main journals, and run as tight as possible without heating. Any lost motion will soon batter out the babbitt or bronze lining. Pack the plungers loosely, so that there is always a small amount of leakage around them, thereby reducing friction and wear. In starting an electric pump: open the priming valve and fill the entire water-end with water; open the by-pass valve; turn on the current and start pump and motor; open air-valves and exhaust all air from pump; gradually close the by-pass valve and note from pressure-gauge that all plungers are working; and when each plunger is doing its portion of work, close the by-pass valve and pump direct into the column. In case one of the plungers fails to deliver its proportion of water, shut the pump down and examine the valves.

The valves should be perfectly tight on the seat, and in case there is a defective bearing it should be turned up in a lathe or fitted with a hand-scraper. An extra set of valves should be available, so that if one valve shows a leak it may be immediately taken out and a perfect one inserted. A valve leak if continued will soon ruin both the valve and seat.

NEW SHAFT-SINKING RECORD REPORTED

The following is from 'Keepintouch', published by the Denver Rock Drill Manufacturing Co. "The world's record for shaft-sinking (until recently held by the Crown Mines of South Africa, where 270 ft. of shaft was sunk in 31 days), has been shattered by our Waugh clipper drill at the Miami Trust Co.'s property, Miami, Arizona. We are informed that the clippers achieved 308.2 ft. through Pinal schist in 31 days, three clippers being employed in the work. Details of this remarkable Waugh record had not been received at the time of going to press, but this much is known: that the

world's shaft-sinking record has been broken, and that the drill that turned the trick was none other than our own little clipper. That is something to puff out the chest of every Waugh-rrior in factory and field."

NEW REGULATOR FOR MOTOR ON PRESSURE SYSTEMS

A new gauge-type pressure regulator is being manufactured by the Cutler-Hammer Mfg. Co. of Milwaukee to replace former apparatus. The new regulator consists of a pressure gauge and relay mounted on a slate panel carried on a wall-type frame, and may be used on either A.C. or D.C. circuits. It is more durable and cheaper than their former types of regulators, the manufacturer claims.

This device is used as an automatic means of controlling the pilot circuits of automatic starters used with motors operating pumps, compressors, etc., and can be used on pressure systems above or below that of the atmosphere. As the pressure falls or rises the needle indicator in the pressure-gauge makes contact with one of two adjustable contact points, thereby starting or stopping the motor when the pressure falls or rises to the points at which the contacts are set. The two contact points can be set as close as

5% of the total reading shown on the gauge, and give practical results, and can be made accessible for adjustment by unscrewing the glass cover of the dial. The pressure inlet hole in the gauge-cover is tapped for $\frac{1}{8}$ -in. pipe. The gauge can be supplied with dials reading in various capacities, the smallest being 0 to 25, and the largest 0 to 10,000, all readings being in pounds per square inch. Dials reading from 0 to 30 in. of mercury below atmospheric pressure can also be provided.

The relay used in connection with the gauge has solid copper contacts, and will operate on either direct or alternating circuits. The relay provides low-voltage release, and will operate to start the motor when the voltage returns. Pressure regulators of this type must always be mounted in a vertical position and should be connected to an independent pipe from the pressure-tank, or else to the discharge line from the pump with an air-chamber interposed between to prevent the fluctuation in pressure produced at each stroke of the pump from seriously affecting the gauge needle.

AN INDUSTRIAL SURVEY OF HIGHWAYS

Agitation by transportation experts of a movement to secure industrial surveys of highways, particularly those linking towns and communities, for the purpose of ascertaining their adaptability to motor-truck transportation for short-haul duty as a relief to congested railroad conditions has aroused a wave of interest among shippers, manufacturers, and truck-makers. The consensus of opinion of men who know the importance of the transportation system in the country's commercial activity, is that the plan will do more than any other factor to solve the shipping problems with which business is confronted. Motor-truck manufacturers, who probably are in a better position than anyone else to visualize the national transportation needs and who

know the tremendous demand for trucks to handle inter-city and inter-community hauling, are unqualifiedly in favor of the project. One of the strongest recommendations for it has been given by E. A. Williams, Jr., president of the Garford Truck Co.

"The plan is one that should be acted upon immediately," Mr. Williams said. "It will, of course, afford some permanent relief from railroad congestion, but it is needed now to take care of the situation that will prevail during the next few years. Railroads are not in normal shape. Private owners, to whom they recently have been returned after more than two years of Government control, will be hampered by red tape in restoring conditions that will even approach normal. In the meantime the motor truck must fill the gap left in transportation facilities."

COMMERCIAL PARAGRAPHS

The United Filters Corporation has moved its Chicago office from the Peoples Gas Bldg. to 1310 Tribune Bldg.

L. T. Pockman has been appointed district manager for the Chicago Pneumatic Tool Co. at Los Angeles, with headquarters at 307 East Third St. Mr. Pockman is well and favorably known among the mining men of the West and his appointment will be of interest to many.

A. O. Gates, sales engineer for the Dodge Sales & Engineering Co., has come to San Francisco to make his headquarters here. He will devote his attention principally to mining and metallurgical equipment and expects to make a trip through Arizona, New Mexico, and Colorado, soon. His office is at 1407 Hobart building.

Bulletin 'P. M. 56' issued by the Worthington Pump & Machinery Corporation aims to familiarize the 'man in the field' with the construction of the Standard McCully gyratory crusher, and give practical information to guide him in its erection, operation, and repair. It is amply illustrated and should be of service to engineers.

Smelting furnaces are among the many products of the Worthington Pump & Machinery Corporation. Bulletin 'P. M. 55' describes blast-furnaces, reverberatory furnaces, water-jackets, forehearths, and other accessories of both lead and copper smelters. Various types and sizes of equipment are supplied by the Worthington company.

B. C. Collier has been elected vice-president in addition to his present position as general manager of the Cement-Gun Co. W. J. Roberts, president of the Traylor Eng. & Mfg. Co., has also been advanced from the position of vice-president of the Cement-Gun Co. to that of president, and S. W. Traylor, formerly president of the Cement-Gun Co., is now chairman of the board of directors.

A. E. Hitchner, former manager of the mining section, Industrial Department, Westinghouse Electric & Manufacturing Co., has become assistant-to-manager, Industrial Department, in charge of mining and chemical industries. After three years as city salesman of the Philadelphia office of the Westinghouse company from 1909 to 1912, he was appointed manager of the Wilkes-Barre sub-office in the centre of the anthracite coal-field. In the spring of 1919 he was appointed manager of the mining section, Industrial Department.

Announcement is made by F. W. Davis, Jr., president of the Detroit Graphite Co., that J. W. Austin has become connected with that company with title of assistant secretary. Mr. Austin is well known throughout the paint and varnish industry, particularly by companies supplying those industries with their raw materials, through his connection for the past twenty years with the Acme White Lead & Color Works. In addition to other duties, Mr. Austin will direct the purchasing policy for the company's plants in both United States and Canada.

T. A. RICKARD, . . . Editor

HOTEL and other accommodations for tourists in Europe are said to be defective and those prompted by curiosity to visit the battlefields of the recent war will have to suffer a good deal of discomfort. We hope they will. This is no time for globe-trotting of any kind, least of all to the countries still nursing open wounds. One does not visit a friend soon after a funeral. Our prosperous citizens will not make themselves liked, despite the spending of money, by poking their noses idly into the sore spots created by the most devastating of all wars. If they must travel and idle, they had better see something of their own country. We recommend them to see the many beautiful and interesting places under their own flag, in the West, in Hawaii, and in Alaska.

SAMUEL MONTAGU & CO., in a recent circular, give statistics of British gold importation and exportation, showing that in March the gold imported into the United Kingdom was valued at £4,199,155, of which £3,664,171 came from the Transvaal, and £270,139 from Rhodesia, whereas the gold exported was valued at £9,054,526, of which £4,336,005 went to India, £2,707,634 to the United States, and £1,470,441 to Argentina, Uruguay, and Paraguay. Thus the export of gold was more than twice as large as the import, and the amount sent to British India was slightly more than the whole amount imported from South Africa and other regions; indeed, the absorption of gold by India is today a large item in hindering the adjustment of the conditions brought about by the decreasing gold output of the world.

VARIOUS erroneous statements are current concerning the market for silver. There is no truth in the rumor that our Government is selling silver to India or to any other foreign government. It is equally untrue that the mint in San Francisco has been closed, except in the usual way for a few days pending the annual clean-up. The drop in price is due to the temporary satisfaction of Oriental requirements; during the War the demand from China, Japan, and India was not satisfied; since then the removal of the embargo on shipments from this country had led to sufficient purchases to glut the market for a time. Germany was expecting to buy silver; she is unable to do so, owing to the delay in the ratification of peace with the United States and her consequent inability to trade freely with this country. These conditions will be rectified in due course. A

price of one dollar per ounce is still being paid for silver by the Director of the Mint, in accordance with the terms of the Pittman Act, whereby he is obliged to purchase all silver tendered to him at one dollar per ounce until the 271 million dollars that have been melted are replaced in the Treasury, provided that silver so tendered to him is not only produced but also reduced metallurgically in the United States; in other words, he will not accept that which is not actually mined in this country. Mexican and Canadian silver can be sold at any price under a dollar to individual purchasers, but all domestic silver is still assured a price of one dollar per ounce. If the price hold at that figure, our friend the miner will not have much reason to complain. 'Dollar' silver used to be his fondest expectation not long ago.

PLANs are completed whereby American copper producers will be able to dispose of their product in foreign markets through the medium of the Copper Export Association. The consensus of opinion is that stocks in Great Britain and France are low, and that, with the completion of arrangements for foreign financing, export business will rapidly deplete the present surplus in this country. The price reported as having been agreed upon is 20 cents per pound, which is considerably below the figure originally proposed. The arrangement provides for 90-day credits, the vendors being protected by deposits of foreign government bonds or by guarantees from French and British bankers. The generally accepted view is that exportation to Japan is out of the question on account of the financial condition of that country. Estimates of unsold metal in the hands of refiners here vary considerably, but it may be taken that there is in stock half a billion pounds, although the sales into consumption since January 1 have exceeded production, and the excess at present is growing steadily with the increase of manufacturing activity. Of course, the rate of production at approximately 50% of normal capacity, which has been maintained by most of the large producers since the beginning of 1919, is not to the liking of the stockholders, and, if continued, can have but one result, namely, greatly decreased dividends. The Jackling companies, for example, each drew heavily on the surplus created during 1915, 1916, and 1917 to provide dividends for 1919, and both Chino and Ray have reduced their disbursements for the first quarter of this year by one-half. They, however, have fared better than

other mines, in Michigan and elsewhere in the West. On the whole, the outlook is encouraging.

IN an advertisement in one of our local newspapers, offering stock in a gold-mining company operating at Grass Valley, California, we note the statement that the area in which the mine is situated "grows richer the deeper you dig". This refers particularly to the Empire, North Star, and Idaho-Maryland groups of mines. It is not true. Moreover, it is remarkable how this ancient fallacy survives, at least sufficiently for the purposes of promoters. The North Star vein has "petered out" at the bottom of the mine, 2500 feet vertically below the surface, and the future of the property in depth depends upon another vein that enters the ground from an opposite direction. Even this is not as rich as was anticipated at the time when litigation with the Empire was avoided by a reasonable compromise. The fact that one or two mines in a given district survive after their neighbors have ended their economic lives is not a proof of enrichment in depth, but is the result of consolidation, smaller overhead expenses, the enlarged scale of operations, and more effective metallurgic treatment. The general statement that gold mines in any district "grow richer in depth" is no more true than the statement that men grow stronger the longer they live.

WHILE politicians are playing with the soldier-bonus proposal at Washington, it is interesting to note the recent utterance of Lord Shanghnessy, a stalwart Canadian whose peerage is significant simply as a mark of honor bestowed upon a man of rare ability and character, born an American and risen from the ranks. The chairman of the Canadian Pacific Railway company remarked: "The American soldier's demand for a \$2000 bonus has its counterpart in the Canadian's claim for \$2500. Canada has provided for her soldiers, their widows and children. . . . We hesitate to comply with a demand which would dim a record as illustrious as the classic glory of ancient Greece, and would entail a greater final money loss on them than any possible benefit. For ourselves we feel that no man who has lived long enough to remember the expanding corrupting pension systems built up out of the Civil War would care to see the experiment tried here." To this we venture to add that not as much has been done for the crippled soldiers and those out of work as might have been done, nor as much as has been done for the Canadian soldiers, and that we hope this national duty will not be neglected; but to pay a bonus to those who went through the campaign unhurt is indeed to sully a splendid performance by measuring it in dollars. It is only one more phase of class legislation, which opens the way for all sorts of political play, hurtful to the best interests of the nation.

FOREIGN trade statistics are informing. The increase of our export trade, in the face of unfavorable rates of exchange, is remarkable. During March, the latest month for which figures are available, Europe took 56% of our total exports, as against 62% last year. The de-

preciation in exchange affected our commerce with Italy and France; in nine months there was a drop in our exports to Italy from 381 to 299 millions; during the same time France imported 565 millions as against 696 millions in the corresponding period last year. Even these decreases are not as large as might have been expected. On the other hand, England took 221 million dollars worth of goods from us in March as against 132 millions a year earlier and as against 169 millions in February, when exchange was at the worst. An increase in the sale of raw materials is the chief fact, our shipments of crude stuff comprising 27½% of our total exports to England in March, whereas a year ago in the same month this item represented only 16½%. The revival of trade with Germany is the more striking; in March our exports thither amounted to \$21,000,000, as against \$18,000,000 in February, and nothing a year ago. In regard to imports, we bought \$85,000,000 worth from England, France, and Italy in March, as against \$26,000,000 a year ago. These figures indicate increasingly healthy conditions and accentuate the wonderfully strong position of the United States in the commerce of the world.

Our Motto

A good wine needs no bush and a suitable motto should require no explanation. Nevertheless, it seems fitting at this time to give reasons for the faith that is in us. "Science has no enemy save the ignorant." It is a true saying and worthy of all acceptance. Time was when the mariner cut down the oak and made him a vessel wherewith to cruise the seven seas; he depended upon the fickle wind to propel his ship and he steered by the light of the stars. As he fared forth across the main and began to make traffic over the waste of waters, he found the need of something stronger than the old wooden boat, something more certain than the stars. His brothers took the iron from the earth and gave him steel to sheathe his ship, they dug the coal from which he drew the throbbing energy that furrowed the wave, they made him a compass whose trusty finger should point a path when the storm curtailed every star. Navigation became a science and naval construction an art. So also those who go down to the mine in ships; to them Science gave tools, energy, and a light wherewith to illuminate the dark places in the earth. The simple digging of ore was well enough so long as the miner did not penetrate far from the daylight, using pick and spade to move the mineral, applying his muscle to carrying the product of his toil and the sight of the ore as the guide to his advancement. But as he burrowed farther, these simple ways did not suffice, he harnessed the horse to his windlass and made a whim, he yoked the oxen to the cart that carried his ore, he compelled the torrent to turn a wheel and drain his hole in the ground. Then, penetrating to a depth greater than the height of the tallest trees, he found simple mechanical methods began to fail, he called on Science for help, for further he could not go alone. Aid was given abundantly. Steam replaced muscle, steel

replaced wood, and engineering took the place of rule of thumb. Far from daylight he penetrated into the adamant heart of the earth, until he walked in galleries a mile beneath his dwelling.

But even that was only a beginning. Science sharpened his tools with the diamond and quickened his operations with electricity. And then with faithful hand and trusty word, she told the miner how to separate the waste rock from the valuable mineral, the dross from the metal. Metallurgy became an art. Nor was this the end. Science did more; in every department of his manifold operations she breathed a system which crystallized into a great industry, orderly as the arrangement of a crystal, smooth as the working of a machine. The prospector became a geologist, the miner became an engineer, the hole in the ground became the basis of a business that supported a vast community. And yet the story is not told, for Science became more than an aid to work, she became a companion in pleasure, a guide, a philosopher, and friend. As the piece of ore is converted to burnished silver, so the old common sense was transmuted to a trained intelligence ready to cope with every problem in life. Man went forth to conquer, first nature and then himself. Self-reverence, self-knowledge, and self-control led him to sovereign power. Therefore, as a child to its mother, as a patriot to his native land, so he who mines the ore, who wins the gold, refines the silver, or smelts the lead, turns to the fairy who has blessed his going forth and his coming home; he honors her ways, which are ways of truth; he follows her light, which suffers no eclipse; and to those that follow he says, "With this sign shalt thou conquer: 'Science has no enemy save the ignorant'."

Our Sixtieth Anniversary

In a young commonwealth, like California, sixty years is a long time, for it includes a period of remarkable development. The 'Mining and Scientific Press' was founded on May 24, 1860; we celebrate the anniversary with this issue. Among the mining periodicals published in the English language, the 'Mining Journal' in London is 56 years old, 'The Mining Magazine' has 11 years behind it, while the 'Engineering and Mining Journal' in New York is our junior by six years. When our paper was founded in 1860 under the name of the 'Scientific Press', it was devoted mainly 'to the interest and advancement of the mechanic and working man'; it sought 'to encourage home manufactures'. When only three years old the word 'Mining' was added to the title by Alfred T. Dewey, who directed the publication for 30 years and is remembered in the name of the company, the Dewey Publishing Co., by which the business is conducted today. Mr. Alfred Hohman, the distinguished editor and proprietor of 'The Argonaut', was associated in the control first with Dewey and then with Mr. J. F. Halloran, from 1891 to 1898, after which Mr. Halloran controlled the paper alone until the present writer acquired it in 1905. Mr. Charles G. Yale was editor from 1871 to 1893. Among the editors in other days were the

late Almon D. Hodges, W. H. Storms, Clarence S. King, and Mr. E. P. Piper, the last being editor now of the best daily newspaper on the Pacific Coast, the Portland 'Oregonian'. The 'Mining and Scientific Press' grew and progressed with the mining industry of the West. To Mr. Halloran it owed a great deal; although not a technician himself, he recognized the growing importance of the application of the sciences to the ancient arts of mining and metallurgy; he gave increasing space to matters of technology, and brought his sturdy independence to the development of the paper, so as to give it individuality and character. When he handed the reins to his successor the time had come to accentuate still further the growing part that science was playing in the winning of the metals. In this respect the 'Press' is like its contemporaries in other parts of the technical field; it has responded to the needs of the time and has reflected the increasing complexity not only of mining and metallurgy, but of life itself. It is the recognition of a larger duty and the awakening to a wider opportunity that has caused a progressive change in the editorial policy of this paper. The crisis of the Great War intensified the development from a purely technical publication to one that ministers to the intellectual needs of technical men. Man does not live by bread alone; the men of the mine and mill, the smelter and refinery, are interested in things other than the digging and reduction of ores. They are citizens in a commonwealth, not mere pawns of industry. The engineer, a term that in its fullest sense includes all those who use technical science in their daily work, has awakened to his larger duties and his ampler scope as a member of the community; he has realized his responsibilities as a citizen and recognized the expansion of his interests as a thinking individual. The 'Press' has become a 'class paper', that is, one published in behalf of a special class, namely, the industrial and engineering group whose particular effort is devoted to the legitimate exploitation of mineral resources, primarily in the United States, but secondarily wherever American initiative has found its way. Anyone comparing our paper as it is today with the one published twenty or thirty years ago will find that the principal change has been in the greater space given to the editorial and discussion departments. The 'Press' has become an organ of opinion as well as a recorder of technical progress. In this respect also it marches with the times, for the spread of education and the increased participation of educated men in mining affairs have called for the expression of opinions by the editor in one department and by the reader in another, both working together in the hope of sifting fact from fancy, truth from fiction, the essential from the non-essential.

Our motto is 'Science has no enemy save the ignorant'; and the science we have in mind is the one defined by Huxley as organized common sense, not the science of the library and the laboratory only, but of the stope and bench, of the intelligent performance of human effort both in the darkness underground and upon the sunlit surface of the earth. Science has given a willing hand

to the deliver in the mine and to the craftsman in the mill, and they have been eager to accept her help. They have asked for the results of research and the records of experience. The 'Mining and Scientific Press' has tried to give them what might serve them best, and to do that it has gone not to the dusty shelves of dead books but to the wells of living knowledge, to the men who have done things, to those in the very van of technical advancement. To the leaders of the profession, to the consultants in mining and metallurgy, to the superintendents and managers of mines, mills, and smelters, this paper is indebted for the steady flow of practical information that it has been enabled to publish. To its readers also it is indebted greatly. As our business manager, Mr. C. T. Hutchinson, says elsewhere in this issue, they are the foundation upon which a publishing enterprise is built. To the editor they are more than that; they are his friends and supporters, they are the source of his strength. Only a few are known to him personally, yet he is conscious of a friendly cloud of witnesses and responds to the larger stimulus of a widely dispersed clientele.

Our paper reaches the remotest parts of the world, wherever the English-speaking people have penetrated in their search for the hidden ore; yet the 'Mining and Scientific Press' is essentially an American paper. At its start it was Californian; later it became Western; today it is American. That affords a scope, in spirit and in substance, large enough for any journalistic effort. It is not circumscribed by the boundaries of the United States, for American enterprise goes ahead of the flag and opens avenues of commerce to the remotest corners of the earth, as Mr. H. Foster Bain, one of our former editors, explains in an article contributed to this anniversary issue. Our country is awakening to a larger responsibility and a wider outlook in its political and economic relations with the rest of the world. It is probable that the next decade will see the American mining engineer taking a part even more varied and exacting than his past participation in Canadian, Australian, and South African mining affairs. In a real sense, the whole world will be his field. To meet the call of his new opportunities he will need more than ever the aid of the newest technical knowledge and the most recent economic experience. It is the mission of the 'Mining and Scientific Press' to adapt itself to the requirements of its readers and adjust itself to the demands of its clientele; and this it cannot do effectively without cordial co-operation between the editor and the engineers, for, after all, the Greek word for editor still holds good, he is the *suntactes*, he who assembles the information. He assembles it and co-ordinates it so that it may perform its service efficiently. On such assistance we count confidently. For the cordial and ungrudging support given to us in the past, we tender thanks most sincerely. In behalf of a long line of editors, some of them now across the range, we thank the thousands of readers by whom this paper has been supported so loyally. Gentlemen, on this auspicious day, we proffer greetings of good-will.

Preface

The four pages that follow typify three great events in the history of our paper. We reproduce two pages of the first issue, which appeared on May 24, 1860. Next we give a facsimile of the 'disaster' issue of April 21, 1906, printed while San Francisco was burning. Last there is added a facsimile of the poster embodying an editorial appearing in our issue of November 10, 1917, that is, during the period of the Great War. A thousand copies of this poster were printed at the request of the War Department of the United States for the purpose of stimulating recruiting in the mining communities. The first article is one that Mr. Hoover wrote for the 'Mining and Scientific Press' of February 21, 1896, a few months after he graduated from Stanford University and while he was at Grass Valley. This was the first that Mr. Hoover wrote for any technical paper. It is interesting in itself, as a note on the relationship between the distribution of ore and the geologic structure of veins in an important gold-mining district; it is doubly interesting as coming from the most striking personality developed during the crisis of the Great War. Our own reminiscences call for no comment, except that the artist has misrepresented the Editor as using a type-writing machine; we would be sorry if this cartoon should lead any young man into the belief that composition is facilitated by the use of a machine; on the contrary, we do all our writing, except ordinary correspondence, in long hand, using a soft pencil. The article by Mr. Hutchinson, our business manager, will please our advertisers, as well as our readers, because it betokens a streak of humor without which life would lose its savor. Mr. Bain sent his contribution from Rangoon, Burma. It is most timely, for at the moment when it went to press the Foreign Trade Convention was in session in San Francisco. In the future, as in the past, one of the most valuable items in our export trade will be the American mining engineer, therefore Mr. Bain's discussion of the opportunities and duties awaiting the members of our profession abroad is highly pertinent. The subject is illustrated further by Mr. Mackintosh Bell's article, describing copper-mining enterprises in Siberia, to the development of which American technical advice has contributed usefully, in cordial co-operation with British technicians. Last, we give a page to the address delivered by a prospector, Jack Mulholland, before the recent mining convention at Seattle. It will serve to remind us all that to the prospector we owe the very beginnings of mining exploitation. Mr. Mulholland is the organizer of a prospecting association that is doing good work in British Columbia, therefore his suggestion that the literature of mineralogy and geology intended for use in the field should not be burdened with too many "jaw-breaking" terms. This will provoke sympathy, as well as a smile, for the prospector is not the only man discouraged from reading scientific books by their clumsy terminology and verbal obscurities. The editorial on our motto is reproduced from the issue of July 7, 1906.

20 " two squares, " "		3.50
Considerable reduction made to permanent advertisers.		

PROSPECTUS.

THE People of California will be pleased to learn that the publication of the above named Weekly Periodical has at length been undertaken, and that the first number will be speedily issued. There is much latent genius in this State, whose discoveries and inventions would prove valuable, both to Professional men and Mechanics; but for the want of a proper exponent, such discoveries and inventions must remain hidden.—The Publishers have undertaken to become this exponent, and will issue a Weekly Periodical in octavo form, to be called the SCIENTIFIC PRESS, to appear every Saturday noon.

The columns will be solely devoted—

I. To the interest and advancement of the Mechanic and Working Man; to instruct them in all that is useful and advantageous to their Trade or Profession, and inform them of all the latest and most approved discoveries in Science and Art.

II. To advance, encourage and protect "HOME MANUFACTURES." The ruinous system heretofore existing in this State, of sending away on an average \$2,000,000 per steamer needs reforming. This State possesses sufficient raw material, with eager hands to labor to transform the same into fabrics. San Francisco, the great Emporium of the Pacific, can and will furnish the coast north and south, as well as the interior, with all the necessary implements.

III. Inventors of useful Machinery and Instruments, will find this the only medium in this State wherein their claims for Patents may be successfully prosecuted. It is therefore requested, that those interested should at once leave with us their plans, drawings and models, with explicit specifications, and such other information as they may possess relating thereto. The Publishers have made arrangements with an able and successful law firm at Washington, as well as in this city, who will, at moderate fees, prosecute the claims of patentees, both in the United States and Europe. The Publishers will attend to all transactions pertaining to the sales of Patent-Rights either here or on the other side of the Pacific and Atlantic. We shall also keep a record of all New Patents entered, as well as those whose term has expired.

IV. The Publishers will give a history of the rise of our Manufacturing Establishments, a complete synopsis of the number of hands employed, articles manufactured, as well as the *modus operandi*, and such other particulars, with illustrations.

The "*Scientific Press*" will be edited by several able and acknowledged writers, whose Philosophical and Scientific acquirements stand pre-eminent here and abroad, who will also reserve to themselves the right of criticizing the Drama, Literary and Musical productions.

The Publishers will issue five thousand copies as a beginning, which will be sent to all parts of the State and Oregon, the Atlantic States and Europe.

GEO. H. WINSLOW & CO.,

GEO. H. WINSLOW & CO.,
Proprietors

READ THIS!—The *Scientific Press* will give every week a treatise upon all the arts, science, trades, and manufactures, which will not only be entertaining but vastly useful. These articles will be written by the most talented men in this State, who have kindly volunteered, and whose literary acquirements stand pre-eminent, combined with a practical and theoretical knowledge of the subjects they may treat of, which will not fail to create the most intense desire for every issue.

J. H. GOVE'S PATENT HAY PRESS.

Our readers will be gratified to learn, through our first issue, the existence of a Patent Hay Press, invented by Mr. J. H. Gove, of California, for which he obtained a patent from the United States Government in March, 1860, through his agents, Messrs. Wethered & Tiffany, of this city. Patent-rights are now being sold to Counties for \$1,000—Solano County being the first to purchase a right. The patent is issued for the usual period, 14 years, No. 27,361, the particulars of which will be found on another page of the *Press*. Arrangements in the Atlantic States for the sale thereof have been effected. The superiority of this machine over others, is amply testified by numerous notices from the press, as well as by certificates from those who have purchased and used it. This machine may be properly termed a combination of the Railway and Lever Press (See cut and diagram.) We congratulate California, and the inventor, Mr. Gove, upon this important labor-saving utensil; may he reap the reward he so justly merits.

It is estimated that this machine can press from twelve to fifteen tons of hay per day, with three laborers and a pair of horses. Mr. Gove has personally worked at the rate of two tons of hay per hour, in this city, making them in bales weighing from 275 to 350 lbs. to the bale, thereby pressing 100 lbs. more hay—contained in less space than a common 200 lb. bale, which naturally enhances the value of the hay—is more desirable for shipment, and creates less wastage. For further particulars, we refer our readers to the patentee, Mr. Gove, or his agents in this city.

(A). The top lid, as shown open, has a cross-bar which serves to be fastened by loops thrown over each end; which connected by means of rods running to the bottom of the press contracting the pressure from the levers (K) in diagram.

(B) The front door, slatted corresponding with the back of the press, the apertures being for passing ropes or wires for the tying of the bale.

(C) An end door, which retains its position by catches on the inside of door (B), and when (B) door is thrown open, end door (C) recedes enough to allow the bale to be extracted easily.

(D) The follower of the press to which are attached the upper end of the levers (K) in diagram, also slatted to correspond with the door (B) and lid (A), allowing the ropes or wires to pass under the bale.

(E) Is a ratcheted pull-lever which serves to throw off the pall from the ratcheted wheel for the purpose of lowering the follower to its original place.

(F) A grooved wheel containing a rope or chain propelled either by manual or horse power, is attached to a center shaft upon which the chains (M) wind in diagram.

(G) In diagram, are iron rails upon which the grooved or flanged wheels (I) move, and form parts of levers.

(H) Are the levers or arms forked on the lower end, within which are placed wheels (L), connected together by a cross-bar.

(M) Are chains connected with the cross bars at the forked ends of the levers (K), thence to center shaft (P), to which shaft the power wheel (F) is attached—thereby winding the chains around the shaft, bring the lower ends of levers (K) together, which forces the follower with great power upwards, until the arms or levers are raised nearly perpendicular.

(I) A rope running in grooved power wheel (F) for the purpose of working the press.

(J) Another rope attached to a lever on top lid (A) for the purpose of opening and shutting the same in filling and pressing.

(K) The levers or arms (K) are so constructed with forked ends, that one pair of them pass each other at right angles at the top, which principle insures greater force and power than heretofore attained.

To the Mechanics and Manufacturers of this State.

Actuated by the noblest motives, and the period being quite propitious—we have resolved to enter upon the labor of publishing an advocate and exponent in your behalf. We say labor, because much requires to be done before the chief ends of your business avocations, rights and privileges are achieved. The abuses heretofore existing in this State, with reference to the workingman and laborer, need strenuous efforts for improvement. Heretofore, but a meager attempt in manufacturing has been carried on, and if any, only such articles which were for immediate use. In consequence of this and the fluctuating times prevalent in this State, the leading manufacturing establishments never have kept any number of hands for an extended period in their employ. The causes are obvious, as every mechanic who has been here but a short time knows. The State being yet in its infancy has therefore demanded but little; the price for labor has necessarily been too high—and, as a general thing, the market has been overstocked. These are some of the chief causes of the mechanics' want of success. To these may be added the want of the requisite material and machinery.

But California has, for its extremely short existence as a State—a matter of ten years or more—created and executed more than perhaps any other State in the Union, or elsewhere. Backed by an indomitable and go-aheadative spirit, possessing more enterprising, and the shrewdest business men that can be found on this globe, she possesses a *literati* for every science and profession. She has also established permanent institutions for the prosecution of the resources of the State, numerous libraries, free schools, and private academies of learning. We have wandered somewhat from our subject, for the reason that what we are about to assert may be more firmly established; it is this: "*We predict that California in less than ten years will be a manufacturing State, notwithstanding the fabulous gold and silver fields with which she is forever haunted and constantly kept in a hot fever.*" The mechanic and laborer have been induced heretofore to search for the precious metal. Some have found it; the most of them had better remained at their workshop. Their hard-earned dollar would have realized tenfold its value in a more permanent investment, such as tools and machinery, real or personal estate, than in purchasing fictitious mining claims, thereby becoming the innocent dupes of unprincipled speculators.

We wish at the same time to be understood, that we do not refer to the actual miners—because they, perhaps, are devoid of a profession or trade—or to capitalists or owners of established mining fields—they can and do find sufficient laborers to work their respective claims.

We cannot deny that it is due to her immense auriferous wealth that California has achieved her great renown in the

world; but we consider that the time has now come when her other immense resources should be worked into fabrics and utensils. Capitalists could not find a safer or more permanent and paying investment. The facilities for exportation are not only extensive and accessible but particularly lucrative and profitable.

The shipments of nearly two millions of dollars bi-monthly, would thereby be materially reduced; instead of the money going out of the State, it would help to establish an exporting community, and would give thousands of eager hands who seek our golden shores employment. Trade would assume a healthier aspect, and be established more permanently. Losses by shipments would be avoided, and the system of monopoly in articles heretofore sent to us and none manufactured would not be heard of; to say nothing of the time lost in waiting for the arrival of merchandise, freight, and the interest of the capital invested in the meanwhile.

J. E. Emerson's Eyeless Pick.

The annexed highly useful Implement, or Pick, was patented by the gentleman who heads this paragraph, in March, 1859. Mr. Emerson manufactured in the city of Sacramento, these Picks, until the 1st of July, 1859, when Messrs. Emerson & Jones disposed of their patent-right for the United States, to Messrs. Nelson & Doble, of this city, by whom the "Pacific Tool Company" has been established. (See

advertisement in another column.) We learn that up to May, 1860, over 300 dozen of picks have been disposed of by them. This firm employs quite a number of hands, who have gained considerable experience in the manufacture of these tools. They have received orders from Oregon, Utah, and the Washoe mines, which serve as a proof of the satisfaction which these picks give. Messrs. Nelson & Doble have received from the Committee of the last State Fair, a very high recommendation accompanied with a silver medal. For further particulars we refer our readers to Messrs. Emerson, Nelson & Doble, 89 Pine street, in this city.

ENGRAVING ON GLASS.—We translate from *L'Invention* the following account (by Mr. Guggon) of a new process of engraving on glass, for printing the patterns for embroidery, netting, crochet, etc., by which it is said that the labor of a month in this kind of engraving can be performed in one day. The process consists in etching by means of hydrofluoric acid which, as our readers are aware, has the remarkable property of corroding glass:

1. *Substances Employed.*—It is known that certain fatty and resinous substances are not soluble in hydrofluoric acid. Among these substances the author chooses the bitumen of Judea, to which he adds one-sixth part of gum mastic (paste in tears); he then reduces the whole to an impalpable powder.

2. *The Design.*—The design is cut in stencil, either in paper, parchment or metallic plate, in a way to cover those portions of the glass which are to be attacked by the acid, and to leave exposed those parts which are not to be attacked.

3. *The Application of the Process.*—The glass is placed horizontally, and varnished with a very thin coating of any fatty substance (the author prefers the essence of turpentine); and the stencil plate is laid on the varnish while it is fresh. The asphaltum powder is then sifted through a very fine sieve over the surface of the stencil plate and the glass, and the plate is carefully removed, thus leaving the powder upon the glass in figures corresponding to the open parts of the plate. The glass is next exposed to gentle heat, which causes the essence of turpentine to combine with the asphaltum and the gum mastic, and the mixture, in melting, fixes itself to the glass.

4. *Treatment by Acid.*—The pattern is surrounded by a ridge of soft wax prepared for the purpose, and hydrofluoric acid, diluted with one-third its volume of water, is poured over it. In about forty minutes the etching is completed.

TO OUR READERS

IN face of the calamity that has befallen the community in which we live, our own loss seems small. Our records, our library, the note-books of the editors, the manuscript ready for the printer, and the whole of the plant in our composing room, all lie buried under the ruins of San Francisco. But, owing to the customary precaution observed by two of us, complete copies of the weekly subscription lists had been

taken to Berkeley, so that we possess that necessary record. Fortunately, most of the members of our staff live at Berkeley, where the earthquake was less severe and where no conflagration followed in the wake of this terrifying occurrence. As the earthquake occurred at 5:15 A. M., and the fire in San Francisco prevented people on this side of the Bay from reaching their offices, most of us were spared the horror of scenes that sear the memory. We are fortunate, therefore, as compared to many of our fellow citizens. And for other reasons. Our plant has been demolished; but this journal is built on nothing so ephemeral as paper, and on nothing so cheap as machinery; it is based upon the support of many thousand readers and subscribers who are never less likely to withdraw their support than at a time of misfortune. The goodwill of the Mining and Scientific Press is locked up in no safe, confined to no printing room; it cannot be shaken by an earthquake or consumed by fire. And, gentlemen, our friends, there is another something that is not destructible by physical misfortune or financial adversity, and that is the spirit that gives life to the printed word.

T. A. RICKARD,

Berkeley, April 20, 1906.

Editor.

TO OUR ADVERTISERS

OUR old offices at 330 Market Street, being in the very center of the most damaged section of San Francisco, have been totally demolished. We have lost our entire mechanical plant, including cuts, half-tones, type and the issue of April 21, which had already been set up; but fortunately, our complete and most recent mailing list has been saved.

We have secured ample offices in the First National Bank Building at Berkeley, which is on the east side of the Bay of San Francisco and close to the terminus of the trans-continental railroads. Through the courtesy of The Standard Publishing Company, we are in possession of proper facilities for printing. The Miehle presses, which will do our work, are new and of the most improved type. We will only be handicapped (for a few issues) by scarcity of paper; the rush of work at the local photo-engraving houses will prevent the use of half-tones with our reading matter, but we have arrangements pending to have this work done at Sacramento, which city was not affected by the earthquake.

We would urge all of our advertisers whose places of business have suffered, to communicate with us at the earliest moment, as our issue of April 28th will afford the best medium for advising their clients the world over of any change of address.

EDGAR RICKARD,

Business Manager.

MINERS ADVANCE!

A TELEGRAM from Major O. B. Perry informs us that the Engineer Corps of the United States Army has been authorized to raise, by voluntary enlistment, a special mining regiment to consist of six companies of 250 men each and to be known as the 27th Engineers National Army. This regiment is now being recruited, the first having been formed and placed in training at Camp Meade, Maryland. The regiment is to be composed entirely of picked men representing various mining districts throughout the country and comprising all the trades and occupations incident to mining. Each company will contain representatives of every branch of mining work so that it can operate as a unit. The men most wanted are experienced miners, both hand and machine drillers, shovelers, trammers, timber-men, track-layers, pump-men, blacksmiths, tool-sharpeners, electricians, machinists, carpenters, surveyors, time-keepers, cooks, shift-bosses, mine-foremen, and top-men. The work to be done is purely military in character, and is what is known as 'first line' work; it consists in the preparation of underground shelters for the fighting troops and the placing of explosive mines. Such work requires a high degree of skill in rapid tunneling and involves the handling of all sorts of material, from clay and chalk to the hardest rock. In addition to the regular engineering equipment, each company will be provided with special tools, such as tunneling and boring machines, drills, compressors, hoists, and lighting sets. Although the chief function of the 27th regiment will be underground mining, the men will be trained to fight as well as to dig; an engineer officer of the Regular Army will be placed in command, the other officers being selected mainly from the mining engineers that have already volunteered and undergone training. Major Perry and Captain W. H. Landers, two mining engineers well known in the West, have charge of the enlistment. Applications should be addressed to the Commanding Officer, 27th Regiment, Office of the Chief Engineers, Washington.

This announcement should meet with a ready response from the younger members of the profession and from the men that are working with them in the mines. It is a gratifying compliment to the mining fraternity and offers an exceptional opportunity to perform patriotic service under favorable conditions. This will not be the first time that a regiment of miners has played a noteworthy part in history. During the Indian mutiny, in 1857, when the residency at Lucknow was defended by the troops under Sir Henry Lawrence, the regiment that held the fort was the 32nd Duke of Cornwall light infantry, known as the Cornish regiment, because it was recruited in the old mining county of Cornwall. They made a victorious stand, largely because they were able to countermine the sapping of the Sepoys. As the chronicler says, "they took kindly to mining." We shall be surprised if some of the American descendants of those Cornishmen do not find their way into the 27th Engineers of the National Army. Brothers of the pick, this is your chance. Assert your manhood. You have been the pioneers of industry in the waste places of the earth. Now it is your privilege to save civilization from the onslaughts of organized hell! Enroll yourselves not only to keep the world safe for democracy but to keep your hearths and homes safe from piracy on land and sea. Miners, follow on!

From the MINING AND SCIENTIFIC PRESS, San Francisco, November 10, 1917

Some Notes on Crossings

By HERBERT C. HOOVER

From the 'Mining and Scientific Press' of February 29, 1896

There occur in a number of mines in the Grass Valley and Nevada City districts certain local variations in the country rock known to the miners as "crossings". The term "crossing" is very unsatisfactory, because it is used to indicate almost any interruption in the course of the vein, whether it be a fault, dyke, or cross vein. But there is a peculiar form of crossing which affords many points of interest, whose origin seems to lie in none of the above causes. They are lenticular masses or streaks in the country rock, crossing the vein at irregular angles, are usually softer than the inclosing rock, schistose in structure, vary from a few inches to several feet in thickness, and extend along the dip of the vein from a few feet to the entire depth of the workings. They present many features of importance to the miner, for not only do they afford an easy channel for cross-cuts, but they may control the extent of the pay-chute, or even the entire vein filling.

The most typical of this variety of crossing are those of the North Star mine at Grass Valley, called to my attention by Mr. Louis Janin.

In the North Star mine there are a number of these crossings, there being as many as four in one level. Some of them extend only a short distance below and above a level, while others extend through several levels, and one, the west crossing, extends throughout the workings, about 2800 feet, and forms the western limit of the ore body.

On approaching the crossing the quartz usually shows one of two phenomena, either splitting into a network of stringers or ending abruptly, but in either case continuous on the opposite side. The crossings thus form either a breccia of country rock or a "horse" in the vein. The network of stringers sometimes extend into the crossing itself for a few feet on either side of the vein, and giving rise to the suspicion that a cross-vein has been encountered.

There are many current opinions as to the origin of these crossings, some contending them to be streaks of decomposition, or that they are the result of shearing by faulting. But neither is tenable in the North Star case, because either theory would necessitate that the crossing extend from the surface to considerable depth; and, moreover, the vein shows no indication of displacement. Therefore, it is necessary to seek some other explanation, bearing in mind that the crossings are older than the fissure, for they are brecciated by the quartz; that they are mere lenses in the country rock, and not due to either shearing or decomposition.

The North Star vein is a true fissure vein, having an east-west strike, a dip to the north of about 20°, and for

the most part in diabase porphyryite.* The vein has been worked for 2800 feet along its dip.

From the cut herewith presented† it will be seen that the rocks in the vicinity of the North Star mine are of two formations, slate and diabase porphyryite. The contact between them runs almost north and south, and passes near the west end line of the North Star ground. The diabase porphyryite is of igneous origin, and has been intruded up through the slates,‡ shattering them,

From Smartsville Folio
U. S. G. S.

forcing long dykes and tongues into their fissures and sometimes completely enveloping large or small masses. Splendid examples of such formation on a large scale occur at Sweet Home Ranch, ten miles south of Grass Valley. And Mr. Lindgren has noted the occurrence of such inclosures of slate in the Ophir district near Auburn.‡

I have microscopically examined slides from some of the North Star crossings and find them to be schist, metamorphosed from slates, which, in connection with their close proximity to the area on the west, and their general parallelism with its strike, make it quite positive that they are merely included masses of these slates.

The character of the fissure varies in passing from the hard, massive diabase to the softer, more blocky slates, much the same as fissures in different country

AFTER SMARTSVILLE FOLIO,
UNITED STATES GEOLOGICAL
SURVEY

*W. Lindgren, Smartsville Folio. Text U. S. Geological Survey.

†The cuts accompanying the article, as published 24 years ago, are reproduced herewith in facsimile.—Editor.

‡Turner, 14th Am. Rep., U. S. Geological Survey, p. 472; Lindgren, 14th Am. Rep., U. S. Geological Survey, p. 253.

§14th Am. Rep., U. S. Geological Survey, p. 253.

rocks. Mr. Lindgren, in discussing the character of Sierra fissures, says: "Different rocks influence the character of the fissure to some extent; in massive rocks they are apt to be straight, clear cut and well defined; in slates and serpentines there is often a tendency to splinter into a network of cracks and fissures extremely small, but often rich." When the North Star fissure passed through the hard, massive diabase it was clean

opposite its foot wall end. In such extensive masses as the west crossing the small exposure along the vein does not show any development, and information is hardly available in the smaller ones. At any rate, the movement has not been extensive, and its greatest effect, probably, was to scatter the crossing debris, some to each side of the crossing itself, thus accounting for the fact that the vein often splits or "raises" around a "horse" before reaching the crossing proper. (See Fig. 3.)

Where the crossings have a limited length along the dip of the vein their effect was much that of a "horse", and the solutions had no difficulty in passing around the ends of this streak of debris in the fissure, but when they are of such general extent as the west crossing they become of utmost importance.

The importance of such a crossing to vein formation lies in its bearing on the distribution and extent of ore bodies in the vein, or even of vein matter in the fissure. That this is of no little consequence is seen from the fact that the plaintiff in the case of Carson City Mining Co. vs. The North Star Mining Co. contended that inasmuch as the west crossing represented the extent of quartz in the vein, it marked the west limit of the vein, and seeks to have the end lines of the North Star readjusted on that basis.

The importance of this particular variety of crossing to the miner lies in the fact that they are often mistaken for faults when they are of considerable thickness and show no well defined walls, and useless crosscuts are run, under the impression that the vein is "thrown". In reality in such cases, not uncommon, the vein is to be found by drifting on the strike of the vein until the crossing is passed, as if it were a dyke. To distinguish between a slate lens and a real fault requires a close study of the country rocks around the mine, and their relations to each other.

In conclusion, then, I think it is evident that some of the crossings are slate inclusions in the prevalent country rocks, and perhaps dykes into slates might produce much the same phenomena; and that it is important that the crossings of every mine be thoroughly understood to more fully determine the extent of any ore body; and that they may be distinguished from faults and the expense of cross-cutting avoided.

Potash deposits were discovered a few years ago in the Province of Barcelona, Spain, near the villages of Suria and Cardona. They consist of irregular beds of carnallite and sylvanite interbedded with rock-salt. Explorations to a depth of several hundred feet show that in the Suria district potash beds occupy an area of not less than 75 acres and occur at depths from 125 to 200 ft. The average combined thickness of the carnallite beds is estimated to be about 56 ft., and of the sylvanite about 13 ft. The Cardona upper beds are interbedded with gypsum and clay, but the lower beds contain nearly pure white salt, which is that principally mined. After the discovery of potash at Suria, these Cardona beds were searched for potash, and nearly pure sylvanite was found.

IDEAL SECTIONS TO SHOW OCCURRENCE OF SLATE CROSSINGS

cut and afforded an open channel for circulation of vein-filling solutions, but where it cut the more blocky slate inclusions the fissure became a network of small veins, thus impeding circulation or checking it altogether, as at the west crossing. Much the same phenomena might be produced by dykes into a slate country rock, the fissure forming after the dykes.

Movement along the fissure probably faulted the lenses so that the hanging wall portion does not hang directly

In 1901, shortly before his death, Richard P. Rothwell, the editor and publisher of the 'Engineering and Mining Journal', asked me to join him as associate editor. At that time I was practising as a consulting mining engineer at Denver, Colorado. I had been a frequent contributor to the columns of the 'Journal' for many years and was a personal friend of the editor, as also of Rossiter W. Raymond, then secretary of the American Institute of Mining Engineers. Dr. Raymond had preceded Rothwell as editor of the 'Journal' and later they had worked together. Soon after this offer of the associate editorship had been made, I had to go to New York, so I availed myself of the opportunity to ask Dr. Raymond for advice. He advised me against an acceptance of the proposal, partly because he thought I would find it difficult to work with Rothwell and partly because the salary mentioned was small compared with my earnings as a mining engineer. My work as a consultant was pleasant and profitable, but it necessitated too many and too long absences from home. I averaged 35,000 miles per annum for 12 years, including two voyages round the world. During the first year after my marriage, in 1898, I was home for more than a week only once. That was one reason why journalism attracted me, apart from the fact that I had learned to like writing and up to that time had contributed enough to the Institute to make a volume of Transactions, having been encouraged to do so by Dr. Raymond, who helped me greatly by his criticisms and suggestions.

Within a few months Rothwell died, after having been editor for 28 years. The 'Journal' passed temporarily into the hands of his executors, John E. Rothwell, Frederick Hobart, and F. J. Pratt. They were intimidated by their unexpected responsibilities and within a few months sold the property to James H. McGraw, who, at that time, controlled the 'Electrical World', the 'American Electrician', and the 'Electric Railway Journal'. Mr. McGraw asked Dr. Raymond to recommend an editor, and he named Dr. David T. Day, then head of the Mineral Resources division of the U. S. Geological Survey. Two years later I asked Dr. Raymond why he had not mentioned my name to McGraw, and he told me that

the reason was his understanding that I did not care to come to New York or accept such an appointment. Rothwell died on April 17, 1901. The transfer to McGraw was made in September. Dr. Day became 'editor in chief' with the issue of September 21, 1901. He appointed Edward W. Parker as managing editor, and it is only fair to Mr. Parker to say that he was the real editor during Dr. Day's incumbency, for the only editorial written by his chief was a paragraph, a 'stick' long, on his favorite topic, 'black sands'. On October 23, 1902, Mr. Parker resigned, having been appointed, by President Roosevelt, a member of the Anthracite Coal Commission; a week later Dr. Day's name ceased to appear at the head of the editorial page; by that time it was known that Mr. McGraw had transferred his control to William J. Johnston, from whom previously he had bought the 'Electrical World', and that changes in the editorship were impending.

The 'Journal' was bought by Mr. McGraw for \$183,000 in September 1901. He sold it to Johnston in the following December, for \$285,000, of which \$200,000 was in notes. Johnston was an inveterate optimist and had a vague idea of meeting the payments out of profits. In 1900 he had bought a paper called the 'Mining and Metallurgical Journal', published at Los Angeles. Soon afterward he had transferred this semi-monthly publication to New York. In the summer of 1901 he telegraphed asking me to become editor; I replied that the only paper of which I cared to be editor was the 'Journal', suggesting that he should acquire it. As a matter of fact, he had tried to buy it from Rothwell, but partly because his terms were unsatisfactory and partly because Rothwell did not like to see the paper pass into his hands, he had failed in his negotiations. Early in January 1902 he telegraphed to me saying that he had purchased the 'Journal', and I replied with congratulations—but nothing more. His name as president appeared on the first page of the issue of January 4, 1902, with the statement, 'with which is consolidated 'Mining and Metallurgy'''. The announcement was made that McGraw would con-

Mr. Parker is now director of the Anthracite Bureau of Information, at Philadelphia.

time as a director of the company. Within a month Johnston wrote asking me to be editor of the 'Journal', and I sent a friendly reply, whereupon he came to Denver, where we made an agreement in February.

When Johnston was negotiating with me, at Denver, he suggested that I should practise as an engineer during three months of the year and thereby add considerably to my salary as editor. To this I replied unhesitatingly that his suggestion was not in the best interests of the 'Journal', that such an arrangement was highly inadvisable, and that I would not be a party to it. He agreed to pay me \$7500 per annum, and it was arranged that I should begin my duties as editor on the first day of 1903. I offered to put some money into the enterprise; he jumped at this, so I gave my check for \$10,000 forthwith and promised \$15,000 more as soon as he would outline his plan of organization. From Denver he went to San Francisco, and, before returning to New York, he asked me to assist him further. I began to suspect that he had not completed the purchase of the 'Journal', although he

par on an 8% cumulative basis. As I had agreed to take 500 of them, there remained 1500. On my return to Denver I wrote to my friends in the profession, offering the preferred stock, which was readily absorbed. Among the 72 subscribers were the leading men in the profession, including R. W. Raymond, James Douglas, A. R. Ledoux, Edward Peters, Anton Eilers, S. F. Emmons, James F. Kemp, J. Parke Channing, Ben B. Lawrence, F. W. Bradley, John Stanton, John B. Farish, D. W. Brunton, F. M. Taylor, J. E. Spurr, E. G. Stoiber, R. A. F. Penrose, H. V. Winchell, Arthur L. Collins, Walter McDermott, Franklin Guiterman, Arthur Winslow, Cortlandt E. Palmer, and A. G. Charleton. Johnston took all the common stock, for it was no purpose of mine to disturb his control as publisher. I asked him for 200 shares of common stock (which I valued then at about \$20 per share) as a commission for helping him to place the preferred. He demurred, whereupon I told him that he was lucky to be left with the control of the business, seeing that he had put only \$85,000 into it. Obviously, I could have obtained control of the 'Journal' at that time with a little financial play, but it would not have been fair to the man whose partner I had become. I endorsed a \$5000 note for him and lent him \$5000 besides. He was in a hole. I had many qualms, I must confess, for I had discovered that he had queer notions of business.

In October I left Denver and moved my household to Staten Island. Johnston and I completed the re-organization, and Mr. McGraw was paid off. This was done during the last days of the month. In the issue of November 1, 1902, it was stated that I was to become editor in January, and that a number of mining engineers had become shareholders, including 2 at Johannesburg, 2 in Australia, 8 in London, 4 in British Columbia, 4 at Butte, 5 in California, 2 at Salt Lake City, 5 in Mexico, 22 in various parts of Colorado, and the remainder in New York, Philadelphia, and Boston. In the issue of January 3, 1903, I made my salutation as editor, and all seemed serene. To tell the truth, at the start I found it irksome to have to write every week, and at first it was not easy to find fresh subjects. Up to that time applied geology, stamp-milling, the sampling of mines, and such matters had been my hobbies; now I found that I had to interest myself in all sorts of new activities and controversies. It gave me as much trouble to write a paragraph then as to write a column now; one has to serve an apprenticeship; most editors have been journalists; I was only a technical writer accustomed to preparing occasional contributions on subjects of my own selection. I had to learn quickly; and I did. My best helper was Hobart; he was an old hand, having been already 10 years with the 'Journal'. He was not an engineer and knew little about mining, but he understood the technique of editing and publishing most thoroughly, and was glad to have me as editor because he knew Rothwell would have approved. Hobart was a veteran of the Civil War, he was a steady and reliable associate editor, and to him the 'Journal' owes a good deal. He retired in 1917, after 24 years of editorial work, and died on March 9, 1919, at the age of 77. When I came to New York to be editor I expected to receive aid

had told me that he had bought it. During the ensuing months I finished my various professional engagements and cancelled my retainers as consulting engineer. In June (1902) I went to New York to make final arrangements. Upon my arrival, we discussed various plans, including a financial re-organization. To my chagrin, I found that Johnston still owed \$200,000 to McGraw, so that his position was precarious. Fearing a divided control, I suggested the issue of \$200,000 of preferred stock, offering to subscribe \$50,000 myself, if he would arrange to include the \$25,000 I had subscribed previously. On coming closer to realities, I found that Johnston's financial affairs were in a sad tangle; he was doing business 'on a shoestring', but as I had become, in effect, his partner, I decided to stand by him. It was agreed that the Scientific Publishing Co., the corporation owning the 'Journal', should be re-organized with 2000 shares of preferred stock and 3000 shares of common, each to have a par value of \$100, making the total capitalization \$500,000. The earnings for the five preceding years had always been slightly in excess of \$24,000 per annum, so I felt warranted in offering the 2000 preferred shares at

and suggestion from that prince of technical editors, Dr. Raymond, but just at that time he was much in need of a rest and went to Europe for a holiday. During his absence I edited a number of the papers sent to him as secretary of the American Institute of Mining Engineers, and in return, as an honorarium, I received a number of back volumes of the Transactions. When he returned, in the summer of 1903, he spoke of my amateurish efforts as editor of the 'Journal' and said that they were 'bully'. Soon afterward I had to decline a series of articles by him on the controversy over Dr. B. E. Fernow and the New York State College of Forestry; and this, to my great regret, caused a coolness that prevented me from asking him for help; but it did not interrupt our friendship.

Our board of directors consisted of five. Mr. Johnston, his son Edwin, and his lawyer (Arthur Palmer) represented the common stock. Dr. Raymond and I represented the preferred stock. When the Doctor went to Europe, Theodore Dwight, his nephew and assistant, filled his place as director. We had hardly established the new organization, in December 1902, when Johnston went to San Francisco, to look after the affairs of the 'Pacific Coast Miner'. He had bought this inconsequential paper from Willard P. Calkins and Thomas D. Calkins. Unable to secure a permanent editor, he had pressed Charles G. Yale, then San Francisco correspondent of the 'Journal', and for 23 years editor of the 'Mining and Scientific Press', into the breach, much against Mr. Yale's wishes. In the January 3 (1903) issue of the 'Journal', there appeared an 'Announcement' stating that Mr. Johnston had purchased the 'Pacific Coast Miner', "which will hereafter be published every Saturday as a separate paper by a separate company, but under a close working arrangement with the 'Engineering and Mining Journal' ". It was stated also that Mr. Yale and J. O. Denny were to be the editors of this "new paper". I do not know why I allowed this to appear on an editorial page; at that time I had no idea of the complications that were to ensue. Johnston was a persuasive man and persistent; it was hard to refuse him politely. In the contemporaneous issue of the 'Pacific Coast Miner' he allowed himself more scope for verbal inexactitudes. On the editorial page, which, however, bore no editor's name, it was stated: "Both the editorial staff and the business staff have been strengthened by combining on the one paper the forces of the 'Engineering and Mining Journal' and of the 'Pacific Coast Miner' ". This was rot, unless he referred to himself as the "forces". We in New York knew nothing about any such arrangement. Next: "The Pacific Coast editor of the 'Journal' joins hands with the editor of the 'Pacific Coast Miner', and both work together—with the cordial and active co-operation and assistance of the editors and special contributors—to produce a periodical that creditably represents the great mining and metallurgical industries of [here followed a list of the Western States] and Old Mexico." I can say unreservedly that "the editors and special contributors",

so airily dragged into this wild-cat publication, knew nothing whatever about the intimate co-operation so positively announced. Johnston's statement, of which Mr. Dwight and I were not aware, as we did not see any copies of the 'Miner' in New York, was unauthorized, improper, and untruthful. His name appeared as President and General Manager. To complete the story, I must quote his description of his own performance, as printed in the same issue of the 'Miner'. It read thus: "After the death of Mr. Rothwell he [that is, Johnston] purchased the 'Engineering and Mining Journal' [he bought it from McGraw after Rothwell had refused to sell it to him] and a year ago merged the two periodicals [the reference being to the 'Mining and Metallurgical Journal' of Los Angeles, which he had bought in 1900]. Since then the net gain in circulation has been just about twice what it formerly was. In addition, the advertising of the

consolidated publication is not only greater than was the aggregate advertising in both papers, but it is fully double the volume that the 'Journal' was carrying at the time of the consolidation." This was characteristic, as I found later; it was an irresponsible exaggeration verging closely upon a glaring untruth, as could be discovered by anybody sufficiently curious to count the actual pages of advertising carried by the 'Journal' at the two periods. These facts have to be stated in order to throw light on the extraordinary tangle into which Johnston plunged the affairs of the 'Journal', and to explain the fracas into which he pulled me.

Mr. Yale attended to the editing of three or four issues of the 'Miner'. Then Louis Janin Jr. became editor, although his name did not appear on the title-page. Mr. Janin came of a family distinguished in the history of American mining and gave promise at one time of a distinguished career on his own account; he had been on Rothwell's staff for a few years, and if prohibition had been antedated, say, 25 years, he would have taken a high place in technology. He is now in a sanitarium in Southern California.

Johnston had an idea, like most of the New York publishers, of controlling a string of papers. So he bought

*"Reminiscences of R. W. Raymond", by T. A. R. 'M. & S. P.', October 11, 1919.

the 'Miner' in San Francisco, and hoped to start another paper in Chicago. He tried several times to buy the 'Mining and Scientific Press', Mr. Halloran tells me. All this he was doing or expected to do without adequate capital. While he was away in San Francisco I discovered, to my horror, that he had used already \$21,000 of 'Journal' money in nourishing the 'Miner'. He telegraphed for a further remittance and our business manager, J. T. Morris, informed me of the fact. The remittance was not sent. Upon mentioning the matter to Mr. Dwight, my co-director, he expressed astonishment, if not dismay. We awaited Johnston's return and then told him that he had no right to use the funds of the 'Journal' in building up a paper in which we had no interest and which in some respects was already a competitor. In order to avoid a personal quarrel, I obtained Johnston's acquiescence to the nomination of a committee of investigation. This committee consisted of the late John Stanton,² a man of the highest standing and prominent in Lake Superior copper mining, Benjamin B. Lawrence, a mining engineer of distinction and now a trustee of Columbia University, and Charles E. Lydecker, then major of the Seventh Regiment and a friend of Mr. Dwight, who himself was in the Seventh Regiment. Major Lydecker, being a lawyer, was of much value in the contingency that had arisen. This committee took a serious view of Johnston's misuse of funds and wanted to prosecute him, but to this step I was strongly opposed, because it would involve the 'Journal' in a public scandal and it would bring trouble upon Johnston's family, whom I knew and liked; moreover, I believed Johnston to be an honest man, but afflicted with queer notions of business; he might be considered lacking in a sense of honor, but he was not dishonest. In the end we settled the matter by compelling Johnston to sign a note for the misappropriated money, the note being secured by 1000 shares of common stock. This gave our party—the preferred shareholders—the control; so we placed Major Lydecker on the board of directors in place of Johnston's son. This was in April 1903. We allowed Johnston to remain president of the company, but the actual control of affairs at this time had passed largely into the hands of Mr. Morris and myself. Luckily for the 'Journal', Mr. Morris was an excellent business manager and supervised the publishing and advertising departments with marked ability during Johnston's alarms and excursions; otherwise we would have been in a bad way.* We were barely able to pay the first quarterly dividend on the preferred stock, on April 1, 1903, on account of the money sent to San Francisco, but the paper was gaining ground and was making increased profits, so we escaped the necessity for telling the preferred stockholders about our troubles. This was a wretched time for me; it was difficult to do my work as an editor, because I never knew from day to day what new difficulty I might have to face in consequence of Johnston's vagaries.

At about this time (probably in June) I received an invitation from Dr. Day to meet him and Mr. McGraw at luncheon at the Engineers Club. Until then I had not made Mr. McGraw's acquaintance. These gentlemen, it appeared in the course of conversation, wanted me to throw Johnston overboard and join them in a new scheme to run the 'Journal'. During Day's absence from the room, I took the opportunity of telling McGraw that I could not see where Day would 'come in' and that I did not care to work with him, but that, of course, I was aware of his own (McGraw's) prestige and ability as a publisher. Day came back to the table, and I then told both of them that although Johnston had broken faith with me and done many queer things, I still felt myself

bound to regard him as my partner and to help him out of the mess in which he had got himself; so I declined their "flattering proposal".

After the settlement in April, we seemed to have sailed into smooth waters, but very soon I found that Johnston was using our lists of possible subscribers and our advertising clientele for the purpose of getting subscribers and advertisements for the 'Pacific Coast Miner'. He promised to cease doing so, but broke his promise; he denied it, and we proved it. Here was another mess. The directors, that is, the three in the majority, insisted that Johnston should get rid of the 'Miner'. We had some stormy meetings. Johnston was in a bad way financially. My friends Dwight and Lawrence thought the time had come to obtain control of the 'Journal' for the mining engineers. We offered him \$50 per share for his common stock; he declined. I suggested that an appraisal be made by three representatives of the publishing business in New York. He agreed. We selected F. P. Burt, manager of the 'Engineering News' and John R. Dunlap, owner of the 'Engineering Magazine'. He nominated E. C. Brown, owner and editor of the 'Progressive Age'. These three agreed to serve as a committee, and in due course, after examining the books of the 'Journal', they reported that \$40 per share was a fair price. Johnston said it was too low and refused to abide by his agreement to accept the appraisal. He told us we could sue him. Again I declined to sanction litigation, because it would entail a scandal. Moreover, I thought myself that \$40 was a low valuation; it was my opinion that the committee on appraisal had allowed their personal distaste for Johnston's methods to prejudice their judgment. Johnston assured me that he could get \$60 for the common shares, whereupon I said that we would give him 60 days

²He died, greatly respected, on February 23, 1906.

*Mr. Morris is now treasurer for 'Public Works', a New York publication devoted to municipal engineering and kindred operations.

to sell at \$60, on condition that if he failed we could have 30 days to buy at \$50. He agreed. This was in November 1903. Here I must note the fact that Johnston's contract with me stipulated that I was to have complete control of the editorial department, so that I was entirely independent as editor, and he had agreed also in the contract not to sell his common shares to anybody of whom I disapproved. I was willing to work with him when I signed the contract in 1902, but not with any speculator to whom he might sell out. So I had a veto.

The first to offer to buy Johnston's interest was John A. Hill, the publisher of 'Power' and the 'American Ma-

chine'. We lunched together at the Hardware Club and had a couple of conferences. I satisfied myself that he was an able man, a strong character, a man of the highest integrity, but rough and overbearing. He was not a man with whom I could work comfortably, and I told him so. He retired. Next came Louis Cassier, of 'Cassier's Magazine'. He wore a handsome fur coat and had an engaging manner. He took me to a bank and I soon found that he expected me in some way to aid him in financing his proposed purchase of Johnston's stock. I declined to do so.⁵ My friend Lawrence made a bet of a dinner for ten that nobody would buy at \$60, and I surmised that he counted upon the persistent use of my veto. Presumably I could have used it to the end of the chapter and enriched poor Johnston out of \$10 per share, that is \$30,000, but I intended to 'play fair', and I had another thought at the back of my head. It was this: during the previous months the control of the paper in large measure had been in the hands of a committee of mining engineers; we had discussed the project of vesting the ownership entirely among members of the profession, which meant that the directorate would consist of representative engineers. I had begun to discern the difficulty of being the editor of a mining paper when the publishers, that is, the directors of the publishing company, were mining engineers. It meant that a small clique would be in control, and they would expect the editor to give heed to their notions of an editorial policy. My idea had been that an experienced publisher should run the business end of the paper and I should be an independent editor, that is, free

from dictation as to policy, always supposing that the policy was not suicidal to the prosperity of the paper as a business. That was why I was willing to leave Johnston in control even after I had found that he had put so little money into the venture, and that was why now I looked with no pleasure to a failure on his part to sell his common stock, and his control as publisher, to a suitable substitute. I accepted Lawrence's bet, believing that the right man would show up. He did. A few days later H. M. Swetland made a proffer of purchase. We had several conferences and lunched together. I found him quiet, sagacious, and frank. He was then publishing the 'Automobile' and two other less important papers. Originally a school-teacher, like Mr. McGraw, he had been manager of 'Power' and the 'Street Railway Journal' in 1886 and sole owner of 'Power' in 1888, becoming associated with Hill from then to 1902. With McGraw and Hill, he had had dealings in the buying and selling of trade papers in New York. They were speculative publishers. Hill was forceful, McGraw shrewd, and Swetland sagacious. I told Mr. Swetland that he was acceptable. Lawrence lost his bet, we dined delightfully with eight others, including S. F. Emmons and James F. Kemp, at the University Club, and Johnston transferred his stock to Swetland. The announcement of the change was made in the 'Journal' of January 21, 1904.

In July 1904 Johnston started a monthly publication

called 'The Mining Magazine' with H. Foster Bain as editor. On the title-page it was stated, "with which is incorporated the 'Pacific Coast Miner'". This magazine must not be confused with the one started in London five years later, although it is noteworthy that Mr. Bain was editor at various times both of the one in New York and of the one in London. Johnston's 'Mining Magazine' ceased to be published in June 1906,⁶ when it was bought by John A. Hill and incorporated with the 'Engineering and Mining Journal'.

called 'The Mining Magazine' with H. Foster Bain as editor. On the title-page it was stated, "with which is incorporated the 'Pacific Coast Miner'". This magazine must not be confused with the one started in London five years later, although it is noteworthy that Mr. Bain was editor at various times both of the one in New York and of the one in London. Johnston's 'Mining Magazine' ceased to be published in June 1906,⁶ when it was bought by John A. Hill and incorporated with the 'Engineering and Mining Journal'.

The transfer of Johnston's stock to Swetland was a great relief to me. Then followed a pleasant time. Mr. Swetland and I worked together with complete harmony.

⁵He was killed in a railroad accident near Salisbury, England, while on his way from New York to London, in 1905.

⁶W. J. Johnston died on April 28, 1907. He was born in the north of Ireland in 1853 and started life as a telegraph operator. His first journalistic venture was 'The Operator', a paper published for employees of the Western Union Telegraph Co. When electricity came into use 'The Operator' became the 'Electrical World'.

I had the fullest confidence in his sagacity and for the first time was able to attend to my editorial duties without fussing with the business administration. The paper prospered; in July we declared a 5% dividend on the common, as well as the usual 2% quarterly dividend on the preferred. But a fresh break was imminent. On the morning after Thanksgiving day, Mr. Swetland came into my office and told me that he had tried to reach me on the telephone the day before and the evening before that, in order to inform me of his negotiations with Mr. Hill. "At 10 o'clock this morning I shall transfer all my stock in the 'Engineering and Mining Journal' to Mr. Hill", he said. "I hope you don't blame me," he added. "Not at all," I replied. "What do you get?" "90 per share," he answered. "Let me see," I replied, "you have received a \$15,000 dividend on your stock, so you have made \$105,000* in nine months. To you it is a matter of business, you have not been with the 'Journal' long enough to have any particular sentiment for it; I don't blame you at all, I congratulate you heartily, but I want to express my keen personal regret that you are going." Not long before, he and I had discussed a purchase of preferred stock by him and of common stock by me, so that our interests might be drawn together, otherwise my policy as a director was inclined to be too conservative, having an eye mainly to the safety of the preferred stock. He had offered me an option on the 200 shares of common that he had bought from me at \$60 when Johnston sold out and I had accepted the option. So, when he announced his sale to Hill, he told me that, of course, it included my 200 shares, on which he would be glad to pay me the difference of \$30 per share. This was right and proper, but everybody does not do what is right and proper amid this flux of phenomena called life, and I appreciated his straightforward action, which was characteristic. Looking back, I regard the departure of Mr. Swetland as a definite misfortune to the 'Journal' and to me. As I have said already, I did not want to be bothered with the publishing end of the business; I wanted only to be an independent editor working in harmony with a capable and trustworthy publisher. Of course, I could have obtained control of the 'Journal' easily during Johnston's aberrancies. The bank asked me how his credit stood; a shrug of the shoulders would have sufficed to shake him out of his precarious position; instead, I endorsed his note at the bank. Only when he proved impossible did I join with my co-directors in facilitating his exit. Mr. Swetland was just the man I wanted for publisher; we worked together charmingly. If he had remained, I might be in New York today. Since then he has proved his unusual ability and has prospered exceedingly, as he deserved.

In due course Mr. Hill made his appearance. After a pleasant greeting, he said, "There will be no changes".

*This, of course, included the advance of \$30 per share on the 3000 shares of common stock.

He is now president of the United Publishers Corporation, which owns 16 papers, including the 'Iron Age', 'Hardware Age', 'Automotive Industries', 'Motor Age', 'Motor World', 'Dry Goods Economist', and 'Lumber'.

This I took to mean that he would not make the changes he had indicated in the course of our conversation the year before, when he had been negotiating for the purchase of Johnston's stock; his remark did not refer to my position as editor, because that was still protected by my five-year contract with the company. Mr. Hill assumed control and soon disclosed his intention to do many things of which I had expressed disapproval to him, such as moving the office of the paper to a large building in the slums, the old Five Points, and consolidating our quarters with those of the other papers that he controlled. I had told him that the supporters of the 'Journal' would not like to see it syndicated and would not wish its identity to be merged in any way with a nondescript publishing business. At the meeting of our directors, Mr. Hill took the upper hand unmistakably and bluntly; if either Mr. Dwight or I had anything to say, he would lay down the law roughly. "What are you going to do about it?" was his retort. He was the boss; he looked upon the preferred stockholders as a nuisance. Soon he suggested dropping the names of our 'Special Contributors', whereupon I informed Mr. Morris,

through whom the proposal was transmitted, that such a change could be made only with my consent, because it affected the editorial department, and that Mr. Hill had better "keep off the grass". In short, we were mutually antagonistic; he regarded editors as necessary evils; I regarded speculative publishers in the same light. To have dropped the names of the 'Special Contributors' would have been offensive to Dr. Raymond, more particularly, but also to others. In November 1904 the names of the following 'Special Contributors' appeared at the masthead of the 'Journal':

R. W. Raymond.....	New York
J. Parke Channing.....	" "
John A. Church.....	" "
Robert T. Hill.....	" "
D. H. Newland.....	" "
Joseph Struthers.....	" "
W. R. Ingalls.....	Boston
Edward D. Peters.....	" "
P. Lynwood Garrison.....	Philadelphia

R. A. F. Penrose, Jr.	..
S. F. Emmons	Washington
Edward V. Parker	..
J. E. Spurr	..
W. H. Weed	..
W. N. Page	Ansted, W. Va.
Robert V. Norris	Wilkes-Barre, Pa.
Philip Argall	Denver
Chester W. Purington	..
R. Gilman Brown	San Francisco
Charles G. Yale	..
A. G. Charleton	London
Henry F. Collins	..
J. H. Curle	..
T. Kirke Rose	..
T. Lane Carter	South Africa
G. A. Denny	..
Donald Clark	Australia
F. Danvers Power	..

Those who know will agree that this was a representative list; it indicated the support of the best element in the profession; it served to emphasize the fact that the 'Journal' had become the organ of the mining profession. Early in February I went to London to attend the annual dinner of my fellow alumni of the Royal School of Mines and while there my friends H. C. Hoover and J. H. Curle suggested that I should get hold of the London 'Mining Journal'; but the idea did not attract me, because mining journalism in London suffered, and still suffers, from the patronage of the promoter and the bribery of the financier. I returned to New York and resumed my work, but without enthusiasm.

At this time Jacob Langeloth, president of the American Metal Company, offered to lend me \$300,000 at 6% to buy out Hill. Mr. Langeloth had been a friend of Rothwell, and I inherited that goodwill, as it were, when I became editor. In those days we did not look upon our German friends of the American Metal Company, even if they were closely connected with the Frankfurt Metallgesellschaft, as the tentacles of a metal octopus; quite the contrary, for many years the metal quotations of the 'Journal' were obtained by Hobart, who had charge of that department, in the course of a visit each Wednesday to our friends at 52 Broadway. I knew Langeloth only as an old friend of Rothwell, and as a kind and courteous gentleman with whom I lunched occasionally, and to whom I related the queer things that had been happening in the course of our troubles with Johnston. When Mr. Langeloth offered to lend me the money to buy out Hill, I had reason to know that the common stock was earning more than 10%, and therefore that after paying the 6% on the loan there would be a margin of 4%, which would be increased if the 'Journal' prospered, as seemed likely. On the other hand, I disliked the idea of incurring so large a liability and of placing myself as editor under such a financial obligation to anybody; so I declined the proposal.⁸

In March 1905 the government of Nova Scotia asked

me to report upon the gold-mining industry of that Province. This meant an examination and report, which was contrary to my self-imposed rule not to practise as an engineer while acting as an editor; so I declined the engagement. My position became increasingly uncongenial; early in April I asked Mr. Morris to tell Mr. Hill that it was advisable in his interest and mine that I should resign, as I had begun to realize a loss of enthusiasm for my work. I intimated that I would do my best, in good faith, until the end of the current volume, that is, to June 30. Each volume included the issues for half a year. Mr. Hill agreed to my resignation, not without courteous protest.⁹

At this period I had already begun to turn my eyes to California, thinking of the 'Mining and Scientific Press' as offering a suitable field for activities that I had learned to enjoy. I had served an apprenticeship of 2½ years on the 'Journal'; I liked the work of editor, and the work seemed to like me. By this time I had made up my mind not to put myself in the position of being transferred like a bushel of potatoes every time that one speculative publisher sold out to another of the same group. Like most educated men, I was willing to work with a competent associate, but I was not willing to be bossed by an uncongenial person, especially one lacking the amenities so necessary to pleasant co-operation. London did not attract me; I did not like the climate; I liked the American way of doing and saying things; and the sinister relationship between mining finance and mining journalism in the British metropolis seemed detrimental to the only kind of journalism for which I cared. So I thought of the 'Mining and Scientific Press'. It was, and always had been, a clean paper. J. F. Halloran, the owner and publisher of it, was known to me pleasantly; I had contributed more than once to the 'Press' when I lived in Colorado, and I believed that Mr. Halloran would regard an offer from me favorably. Besides, the idea of living in California, particularly at Berkeley, was attractive. I had been in charge of a gold mine (the Rathgeb or 'Union Consolidated' property, near San Andreas) in Calaveras county from 1887 to 1889 and I had examined mines in other parts of the State in later years, so I knew something about local conditions on the Coast. My grandfather, James Rickard, had come to California in 1850 to examine the Mariposa estate and he had erected the first stamp-mill in California. This was a sectional plant brought by him across the isthmus of Panama from Cornwall and erected near Coulterville, in order to test the ore of the southern end of the Mother Lode. He made the examination for John Taylor & Sons, a firm still honorably prominent in London, on an option held by General John C. Frémont, the Pathfinder, and candidate for the Presidency of the United States in 1856. Capt. James Rickard, as he was called, being a senior mine captain, reported adversely on the Mariposa grant, after an investigation that lasted six months. My uncle, Reuben Rickard, had been president of the town council of Berkeley in 1888, and his son, Thomas Rickard,

⁸Mr. Langeloth died on August 14, 1914.

⁹John A. Hill died on January 24, 1916.

was elected mayor of Berkeley in 1905, so I had many pleasant ties to draw me to California. Therefore I wrote to my friend Ben S. Revett, the specialist in alluvial mining, then sojourning in San Francisco, and asked him to interview Mr. Halloran in regard to a possible deal. He found Mr. Halloran rather coy; in the first place, the publisher of the 'M. & S. P.' was sceptical as to my ability to find the necessary money and suspected that I represented some syndicate or group; he did not know that during my years of professional practice in mining I had done so well, although, of course, my earnings were small as compared with those of successful engineers nowadays. However, Mr. Halloran expressed willingness to deal with me personally and suggested that I meet him in San Francisco. That was impossible, because I had to attend to my duties on the 'Journal', so we compromised, and I agreed to meet him at Chicago. This I could do without losing any time.

It happened that the American Institute of Mining Engineers held a meeting at Washington on May 2 and the following four days. I went to Washington, where my wife and I were guests of Mr. and Mrs. A. A. Blow, old Colorado friends. The meeting ended on Friday, and on the afternoon of that day I went to Chicago, meeting Mr. Halloran on Saturday evening, May 6, 1905. I reached New York on Monday morning, so that nobody in the 'Journal' office knew that I had been to Chicago.

Mr. Halloran and I did not take long to make a deal, for both of us knew what we wanted to do. He asked me how I based my valuation of the 'Press', and I said upon the average earnings of the previous five years capitalized on a basis of 15%. He told me what the earnings had been and I offered him \$121,000 for his two-thirds of the stock, this being based, if I remember correctly, on average annual profits of \$24,000. He asked \$125,000, and I agreed. He said that I must put up \$10,000 then and there, and I agreed to do that. Then I told him that, of course, I would like, as a formality, to have the books of the Dewey Publishing Co., in which the ownership of the 'Press' was vested, examined in due course by an accountant. "If there should be any inadvertent error in your figures of the earnings, what happens to my \$10,000?" I asked. "You forfeit it," he replied. To which I retorted: "Oh, I see, you want me to bet \$10,000 that J. F. Halloran is an honest man; I'll make the bet." This was Western.

So was the whole deal. At the back of my head, besides confidence in Halloran's good faith, was an idea that if anybody got \$10,000 out of me on a mis-statement, I could recover. He asked whether I wanted a lawyer to draw up our agreement; I said "No; you draw it up". He did; I accepted it; we went to a notary in the hotel, Halloran paid him 25 cents, and the deal was consummated. Further payments were due in July and November. Halloran held two-thirds of the 750 shares, of \$100 each, for which the company was capitalized; the other third belonged to a very old man, Warren B. Ewer. It may be best at this point in the story to state what happened to that interest. On my arrival in San Francisco I tried to buy it, through Ewer's representative, a lawyer named C. E. Naylor, but I was informed that Mr. Ewer had confidence in my control and did not wish to sell. I feared some speculator, uncongenial to me, might buy the stock, so I told Mr. Naylor that I disliked having a sleeping partner and would feel justified in taking a large salary. After protracted negotiations, ending in March 1906, I bought the Ewer third for \$75,000, of which \$15,000 was in cash and \$60,000 on a note at 8%. Mr. Ewer declined to sell for cash, so that was the best I could do.

I have not finished my account of the negotiations with Mr. Halloran at Chicago. I told him of my distaste for doing anything spectacular, such as leaving the editorship of the 'Journal' one week and assuming that of the 'Press' the next week; I desired a decent interval to elapse; in short, I wanted him to continue in charge of the 'M. & S. P.' I asked him what salary he was paying himself; he said \$100 per week, whereupon I told him that I would be much obliged to him if he would continue to run the paper for the rest of the year (eight months) as if nothing had happened. He agreed. I returned to New York. Mr. Hill asked me to suggest a successor; and I told him that W. R. Ingalls was the logical man. Mr. Ingalls had been the most voluminous and most valued contributor, outside the staff, for several years, and he had kept so close a touch on worldwide progress in metallurgy, more particularly, that evidently he was the man to appoint. As he lived on Staten Island not far from me, I walked over to his house one afternoon in May and told him of the impending changes, much to his surprise.

Immediately after I left the 'Journal', Mr. Hill ceased to print the list of Special Contributors on the first editorial page and proceeded to buy the preferred stock. I sold mine at \$105; all my friends obtained par or better for their shares, some as much as \$112.80. Mr. Hill succeeded in buying the whole of the preferred stock, indicating thereby the low value he set on the direct support of the profession. The 'Journal' ceased to be the organ of the mining profession and became one of a syndicated group of trade papers.

My valedictory—a short one—appeared in the 'Journal' of June 29, 1905. A few days later I went to Halifax, for, as soon as my resignation as editor became known, the invitation to make a report on the gold-mining industry of Nova Scotia was renewed. I made a

preliminary inspection and agreed to do the work in August. Then I went to San Francisco to see Mr. Halloran and make the second payment on the 'M. & S. P.' Everything went smoothly. I spent August and part of September in Nova Scotia. Early in October I went to Mexico, spending four weeks on visits to El Oro, Pachuca, and Guanajuato, as recorded in 'Journeys of Observation'. On November 10 I reached Berkeley, whither my wife and children had preceded me, establishing themselves in a house that I had selected and leased when in California during the previous July.

While at Guanajuato I received a telegram from my cousin, Edgar Rickard, who had just returned to Berkeley from Baja California, Mexico. He said that he had heard of my purchase of the 'Press' and offered to be business manager. I replied that I would be glad to have him, if we could agree on terms. We did, readily. He had been associated with me in my professional practice when in Colorado. He was a graduate of the University of California and had a host of friends in San Francisco. He took charge of the business department of the 'M. & S. P.' on December 1. At that date Mr. Halloran resigned as president of the company in my favor and Edgar became director in lieu of Harry Durbrow. On that day I informed Mr. Halloran that my friend William Hanson (manager of the California Wine Association) had examined the books and reported that, although the statement as to earnings was approximately correct, the accounts showed that the cash on hand at the end of the five-year period was less than at the beginning, so that the earnings of the paper during that period actually were a little less than the figure given to me by Mr. Halloran. Whereupon Mr. Halloran began to say something, but I interrupted him by stating that I had only mentioned the matter in order to show my knowledge of the fact and to emphasize my satisfaction with the deal, more particularly the manner in which he had performed his part, in managing the paper with such sincerity in my behalf during the preceding months. We then shook hands cordially. Just as we finished the transfer of the property, an earthquake shook the building, at 330 Market street. Mr. Halloran exclaimed jocularly: "That always happens when the 'Mining and Scientific Press' is transferred." On April 18, 1906, San Francisco was shaken by a severe earthquake and devastated by a conflagration that lasted three days and three nights. The entire plant of the 'Press' was destroyed. I was paying 8% on the \$60,000 note to Ewer. Things looked black; but not for long. We were soon on our feet again.

The earthquake arrived at 5:13 in the morning; by noon we knew that our offices and plant had been destroyed; but we had the essential asset, our subscription-list; the one for that week Edgar R. had taken home with him the night before and the list for the previous week was at my own house. All we needed was an office and a printing-press. By three o'clock that afternoon we had leased a suite of rooms in the new building of the First National Bank at Berkeley, where both of us were living, across the bay from San Francisco, and two hours

later Edgar R. had arranged for the setting of type and the printing of the 'Press' by a local newspaper, called 'The Reporter'. We bought some furniture and engaged a number of refugee girls to address envelopes, for we anticipated that for a time nothing would go forward except by first-class mail. We bought the whole stock of stamped envelopes at the Berkeley post-office. Early that morning, while waiting to join forces with Edgar R., I had written an article on earthquakes and

had it ready for publication. The earthquake was on Wednesday; the burning of San Francisco continued until Saturday; an emergency issue of the 'Press' (dated April 21) was posted at 5 p.m. on Friday, April 20, so that just when all our subscribers thought the paper was 'down and out' they received a cheerful greeting. We never missed an issue! The next one, that of April 28, was of regular size, but it was unusually interesting on account of various illustrated articles on the earthquake, besides the usual quota of mining news and technical information.¹⁰ We were weeks, even months, ahead of other publications in San Francisco. The reader will forgive this boasting! 'The Reporter' cinched us, but not so badly as the Oakland 'Tribune', which charged us five times the usual price for half-tones; so we had them made for us at Sacramento, Los Angeles, even Chicago, until the engraving establishments in San Francisco got to work again. In July we had our own composing-room once more, in Berkeley, and in September we began to have our printing done in San Francisco, sending the 'forms' to the Stanley-Taylor Company by automobile and ferry 12 miles across the Bay. At the end of April 1907 we moved back to the City, with quarters in a little brick building at 667 Howard street, amid the dust of ruins and the din of reconstruction. A year later, in May 1908, we sold 'The Rural Press', a paper devoted to the industry of agriculture and a younger brother of the 'Mining and Scientific Press', having been founded by A. T. Dewey and Warren B. Ewer in 1871. Edgar R. and I took no interest in it, and were glad to sell it for \$4000 to Frank Honeywell. With the proceeds we bought a linotype machine. Up to that time, May 1908,

¹⁰A full account of those exciting days will be found in my article 'The Earthquake Fire', published in our 50th Anniversary number of May 21, 1910.

our type had been set by hand. In August 1911, the 'Press' moved to its present offices, at 420 Market street. That ended the migrations caused by the earthquake-fire of 1906. Reverting to that event, I may state that we had paid a 2½% dividend four days before the catastrophe. I had invited half a dozen friends to become shareholders. One of them was H. Foster Bain, then State Geologist of Illinois. In my first mail after the earthquake I found a check for \$500 from him. That looked large just then, for all our local banks were closed. I wrote back to him saying that under the altered circumstances of the 'Press', he would probably like to withdraw his subscription and I would return his check. He replied promptly saying that he would take his chances. Three years later (on April 3, 1909), he became associate editor of the 'Press'.

A year earlier Courtenay DeKalb joined me as associate editor, and when I went to London in 1909 he and Mr. Bain became joint editors of the 'Press', until Mr. DeKalb resigned in July 1910. After that Mr. Bain was the editor until my return in March 1915. Mr. Bain is a facile and agreeable writer, and a man rich in friends. Mr. DeKalb was, I believe, the most scientific and literary man ever on the editorial staff of any mining paper. As an example of his style, I like to recall the editorial entitled 'The Curse of Potosi', published in the 'Press' of July 4, 1908. In that editorial will be found his characteristics: fluent diffuseness, literary charm, sympathy with the Latin races, knowledge of South America, all commingled in producing a kind of writing rare indeed in technical publications. Mr. DeKalb rejoined me in March 1917, remaining as associate editor until he went to Spain on a special mission for the Department of Commerce in March 1919.

Early in 1909 I was urged by sundry friends in London, some of them Americans, to start a real mining paper in that city. Edgar Rickard thought it a good idea. It promised to be an interesting adventure. The 'Press' seemed to be firmly on its feet and doing well. DeKalb and Bain were associate editors, and I felt that they could conduct the editorial department satisfactorily. Edgar R. chose Lester A. Greene, our agent in Chicago, to succeed him as manager in San Francisco. In March 1909 I asked Edgar R. to go to London and ascertain for himself what were the conditions affecting publishing, such as the cost of paper and of printing, so that we might know what factors were favorable. As for the editing, I believed that the conditions would be much the same as in San Francisco and New York, except that the centralization of the British mining business in London would make it easier than in either of the American cities. He went and came back within six weeks, bringing a favorable report. We decided to make the venture. Together, with our families, we left California on May 7 and reached London on June 5. Two months were spent in preliminaries. Before our arrival we had decided to publish a monthly magazine and had arranged with Edward Walker, London correspondent of the 'M. & S. P.', to issue a sheet under that name so as to hold the title. We found that others, to block us, had registered

the name 'Mining and Scientific' and one or two other likely names, in anticipation.

On September 15 the first issue of 'The Mining Magazine' appeared. In size and general appearance it looked American: we used calendered paper, plenty of illustrations, excellent printing, and an outspoken style in the editorial utterances, of which there were many. Seven pages of 'Review of Mining' were followed by 14 pages of 'Editorial'. Then came 12 pages of 'Special Correspondence' from Johannesburg, Mexico, San Francisco, Denver, New York, and Cornwall. Two pages of 'Discussion' followed. Among the articles was one by H. C. Hoover, written under the pseudonym of 'A Professional Speculator'. It appraised a number of representative mining shares and created a great deal of comment. J. H. Curle wrote on 'West African Mines', H. F. Collins on 'Sintering of Copper in Spain', and T. Lane Carter on the 'Metallurgy of the Rand'. It is interesting to note that this first issue contained a technical description of the first flight across the Channel by Louis Bleriot, for which I had obtained details from A. E. Berriman, now recognized as a leading authority on aviation. At that time he was editor of 'Flight'.

This first issue was well received, but one or two of our friends suggested that the standard was too high to be maintained. Yet we improved upon it. The 'Magazine' was on its feet and earning a profit within a year; it was a successful venture, but never a large business. It was capitalized for 15,000 £1 shares of 6% preferred, of which only 13,000 were issued and only 10 shillings per share called up, so that we started with a working capital of £6500, of which only £4200, say, \$20,000, was used in establishing the magazine. I subscribed for 5000 of the preferred stock and Edgar for 2000, the remainder being distributed in small holdings among 30 mining engineers, the leaders of the profession, including several Americans resident in London at that time. The common stock, 10,000 shares of £1 each, was divided between Edgar and me. Within three years the magazine paid 10% per annum on the common stock, as well as 6% on the preferred, but even at that the earnings were small. The business never began to compare in importance with either of the two American mining papers. In 1913 I thought of retiring as editor, and even went so far as to negotiate with Ralph Stokes to succeed me. He had been our correspondent at Johannesburg and was one of the few engineers possessed of the kind of critical faculty needed for editorial work; besides, he was a man of quick wit and wide experience. He decided to stick to engineering work and joined W. W. Mein in New York. As soon as England declared war he enlisted, and served with great distinction, rising to the rank of Lieutenant-Colonel and winning several medals for courage and skill. At the beginning of 1914, Edgar Rickard, who had become a close friend of Herbert Hoover, was offered a directorship in one of Mr. Hoover's companies, but when I pointed out that it would entail his resignation as business manager of the 'Magazine', he declined the offer.

The curse of technical journalism in London is its

intimacy with company finance. Most of the papers live largely on company meetings, that is, the payment they receive for publishing reports of the proceedings, more particularly the chairman's speech, at the annual meetings. Usually they are published in the body of the reading-matter like *bona fide* news, but they are printed at the advertising rate, if not a higher one. When we started the 'Magazine' we made it a rule that a company meeting should appear as advertising matter, as indeed it was, because we were paid for it. We charged exactly the same rate for it as for an advertisement of machinery. Even when treated frankly, this sort of business is a sop to Cerberus; it still serves a sinister purpose, because any editorial criticism of the management of a company is likely to be followed by a cancellation or withholding of the order for the advertising space required in reporting the next meeting of the company or of one in the same group. I used to attend the more important of these annual meetings myself and write editorials on them, describing the incidents and recording impressions as if I were telling somebody at a distance what really happened. That was real journalism; I ignored the accounts given by the secretary of the company to the press; I told the true story, which often happened to be amusing as well as significant. As an example of the sort of thing that happened, I may mention the annual meeting of the Consolidated Gold Fields of South Africa in 1913. Several attacks were made by shareholders against the board of directors, but they were poorly delivered. The Gold Fields people had been doing some shady business in share speculation. I said editorially: "Lord Harris took the unction to his soul that he and his colleagues were acknowledged as fair and honorable in their corporate dealings in mines. We happen to know that the general opinion of the mining profession, particularly those acquainted with the performance of the Gold Fields in Rhodesia and Nigeria, is nothing like so kindly." This was true, and it was said in the public interest. A few days after our issue of December 1913 had appeared I received a call from the secretary of the Lena Goldfields, another of the companies of which Lord Harris was chairman; he upbraided me for giving offence to my "friends" and at the same time cancelled an order for 3½ pages (worth £35) for a report of the Lena Goldfields meeting. I told him that by "friends" he must mean 'patrons', that he entirely misunderstood our kind of journalism, which depended for its financial success not upon the patronage of promoters, but upon the fact that it was read by the mining engineers who placed the orders for the machinery that was offered for sale in our advertising pages; in other words, it was a medium of publicity for manufacturers, not a dependent of the *haute finance* of stock-jobbery. This is the sort of thing that mining journalism in London has to face: the gutter press of London lives on it; the best papers have to take cognizance of it; it has been the bane of mining journalism, and apparently will continue to be so. Since I severed my connection with the 'Mining Magazine' that publication has been obtaining a large increase of revenue from this source, chiefly because incisive criti-

cism of company affairs is no longer characteristic of its editorial pages. From my own point of view, the 'Magazine' is not performing one of its proper functions; it is losing its independence, without which journalism of any kind is not worth the paper it consumes.

Meanwhile the 'Press' was going down-hill. Until 1910, even until 1911, the 'Press' did well, but from then it began to decline in its earning power. In 1913 it paid 5%; after that there were no further dividends

-the friends of Lord Harris
are offended!

until 1917. In the summer of 1914 I realized that things were in a bad way; suddenly the War broke out; I wanted to conduct the 'Magazine' until it was over and hoped that Edgar would go to San Francisco, but he had become associated with Hoover's splendid work in behalf of American refugees and then of the Belgians, so I realized that I would have to go to San Francisco if the 'Press' was to be saved. In the first days of February I went to New York to meet Mr. Bain, who had been in charge of both the editorial and business departments since the dismissal of Greene the year before. Our meeting was unproductive of any suggestion or plans for resuscitating the 'Press', so I returned to London to say goodbye to my friends and clean up odds and ends of private business. I made the round trip to New York from Liverpool on the 'Lusitania'; it was on the return voyage that the American flag was hoisted in order to gain protection from the German submarines. On March 6 I sailed again for New York, arriving in San Francisco on March 23, 1915.

The 'Mining Magazine' was a *succès d'estime*, but it was a rash journalistic adventure on my part, because it led me to give all my time to an investment that involved only one-sixteenth the money I had put into the 'Press'. It was good fun, however, and enriching as experience, particularly of men and mines in a world-wide way, for the mining finance of London had a geographic amplitude like that of no other city in the world. On leaving London I exchanged my common stock in the 'Magazine' for Edgar Rickard's shares in the 'M. & S. P.'. He continued to manage the 'Magazine' for a couple of years longer, when he sold out to W. F. White. Mr. Bain succeeded me as editor, but he remained in London only a year, being followed by Edward Walker, the present

editor, who had been my most loyal and efficient assistant for six years. The one excellent feature of the 'Magazine' for which Mr. Walker was personally responsible was the 'Précis of Technology', a compendium of abstracts of technical articles in other papers and periodicals. This was much the best of its kind ever published. Mr. Walker did not merely give excerpts from an original article, he gave the gist of it conscientiously, writing it in long hand, and producing a peptonized version, rendered more easily digestible by references to other and previous writings on the same subject. It was genuine journalism of a rare sincerity.

On arrival in San Francisco in 1915 I found the 'Press' in a bad way. We were losing over \$1000 per month. Our subscription list, as a Cornishman would say, had 'gone seat'. It is unprofitable to cry over spilt milk, but it is wise to learn from mistakes. The business management became inefficient after Edgar Rickard went with me to London. Greene was a good advertising agent at Chicago but a poor executive in San Francisco; he was out of his depth. The editorial work was only fairly good; Bain was deservedly popular, but he lacked the critical faculty, without which no man can be an effective editor. He and DeKalb did not work well together. Moreover, the revolution in Mexico hurt the 'Press', because many of our advertisers did business there. One good thing was done just before my return; that was the appointment of Charles T. Hutchinson as business manager. The appointment ought not to have been made just before my arrival, and that almost queered it; but I decided to accept the situation, rather than cause further disorganization. Soon I found that a bit of real luck had come our way, for Mr. Hutchinson proved himself admirably fitted for his work from the start and I have every reason today to thank the fortuitous circumstances that brought us together on the staff of the paper. The evidence of loyalty and skill in the business chief was a source of much encouragement during the two trying years that followed. I had to carry the burden of the editorial work, which on my arrival was increased by printing four pages—instead of three or less—of editorial criticism and comment in each issue. I had been in touch with the issues of the War from its beginning, but as the United States was neutral, I could not, at first, write on the subject in the 'Press'. When, however, our country entered the conflict, I was permitted to speak out, and did so gladly. Some readers did not like it and cancelled their subscriptions; they were mostly of German origin. I could have given their names and addresses to the proper authorities. Instead, I forgot them. The articles on the great issues arising from the War helped our circulation. Then there was flotation. E. H. Nutter, of the Minerals Separation company, undertook to tell me not to publish a certain article, namely, the interview with Charles Butters, appearing in our issue of August 29, 1915. From that moment I determined to publish as much as I could on a metallurgical subject that I foresaw would be of the most timely importance to our readers. Within two years we published enough material to make two books on flotation, both of which

sold 'like hot cakes'. On January 1, 1915, we had 4318 subscribers of whom 27.55% were in arrears; on January 1, 1917, we had 6214 subscribers of whom 7.62% were in arrears; our effective circulation was doubled in two years. The War called for an intensive production of metals; this stimulated mining, and therefore increased the demand for a technical paper like the 'Press'. At the close of the War a controversy arose between our Western miners and the Government at Washington over compensation for loss caused by the sudden collapse of the market for the secondary minerals used in the manufacture of munitions. The mining of these minerals had been stimulated by the patriotic urgings of officials connected with the Geological Survey and the Bureau of Mines, as well as by the Secretary of the Interior. It had been stated publicly, by these officials, that there was a great need for particular minerals, such as chrome and manganese, and that the miners could depend upon finding a sale for their products. Our paper supported the reasonable claims of those who were entitled to compensation and I deputed Mr. DeKalb to go to Washington, where he remained four months, for the purpose of aiding other representatives of the mining community in placing the matter effectively before the committees in both houses of Congress. In the end a relief measure was enacted, and a commission is now engaged in adjudicating claims. The expenses of publication, particularly the cost of paper, postage, and printing, increased greatly during the War, and since, but our business has prospered. In July 1919 Mr. McGraw, representing the McGraw-Hill Publishing Co., now controlling the 'Journal', opened negotiations for purchasing the 'Press', and consolidating it with the 'Journal'. The negotiations ended in a pleasant game of golf. The 'Mining and Scientific Press' is 'going strong'; it has an identity and a character established by its 60 years of honest effort; on this auspicious anniversary I salute the motto that serves to symbolize the activities of our institution: "Science has no enemy save the ignorant."

'TIN CANS' that used to be wasted to a large extent are now put to use. One plan is to recover the metallic tin. A patent granted to Daniel A. and Sidney H. Wilcox, of Garden City, New York, for a method of separating iron and tin is based upon the fractional distillation of their chlorides. The scrap to be treated is compressed and heated to a temperature bringing a vigorous reaction when chlorine is passed over the metal, both metals being volatilized as chlorides. The scrap may be melted and the chlorine passed through or over the melted metal contained in a bessemer converter, reverberatory, cupola or blast-furnace, electric melting-furnace, or muffle-furnace. By either method the mixed chlorides are separated by fractional condensation and the tin chloride may be converted into metallic tin or tin oxide. The ferric chloride is dissolved in water, reduced to ferrous chloride by passing the solution over hot iron, and electrolyzed, insoluble electrodes being used, so that the products are pure iron and chlorine gas, which may again be utilized.

Why Is The Mining and Scientific Press?

By CHARLES T. HUTCHINSON

Nothing short of the celebration of a sixtieth anniversary can explain or, perhaps one might say, condone, the injection of business within the sacred precincts of the editorial section of this paper. The editor is a kindly, tolerant gentleman, who is gentle and considerate to the business staff, but when it comes to space—well, "My dear sir, you may have all the space you like in the advertising section, provided, of course, it is duly paid for according to the statutes made and provided."

This, however, is a great occasion. "We", editorially speaking, are 60 years old, or young, as the case may be. Where are the editors of yesteryear? Gone, one after another, to the great beyond, where there are no labor-unions to strike, no paper-mills to squeeze out our life-blood with their enormous prices, no excess-profits tax, no postal-zone system of second-class rates, nothing but one 18-hole course after another with cherubs for caddies, balls from the starry firmament, and non-leakable fountain-pens. The business staff, alas! their mortality is higher than that of editors.

Who gets the business, pays the bills,
Finds the paper, cures all ills,
Writes the ads of smelters, mills?
The Business Staff.

George Fitch once said that an editor was a tired, nervous man, who spent all his nights trying to get things into a paper, and his days explaining how they happened to get in. With the business staff all is different. Their days are just one long sweet song, a continuous round of luxurious offices, good cigars, expensive luncheons at clubs and cafés, with the triumphant return about four in the afternoon with a sheaf of advertising contracts amputated from the bodies of manufacturers, accompanied by a smile on the face of the amputatee indicating that the operation was successful even if the patient sometimes dies of the shock. At least, this seems to be the popular misconception on the part of those who are on the outside, looking in.

How often have we (still the assumption of the royal and editorial prerogative) had otherwise intelligent gentlemen stop us on the street when we were hurrying with harassed expression to try and grab a few reams of paper before it was gobbled up by someone else, or to pacify some irate advertiser who objected to the mis-spelling of his name on the front cover, and say something like this, "Gee, what a snap you fellows have got. Nothing to do but sit around all day and collect the money that the world of advertisers insists upon forcing upon you. I wish that I had a job like yours at an enormous salary and nothing at all to do."

Nothing at all to do! Listen:

Why is the 'Mining and Scientific Press'? We hasten

to answer. Anyone can engage in the publishing business, or even publish a mining paper. All you need do is publish such interesting, useful, and instructive matter in such an attractive manner as to make every mining engineer, mine-manager, metallurgist, and chemist simply pass sleepless nights until he can subscribe. Then, when the subscription harvest has been garnered, convey, intimate, or permit news of this accomplishment to leak out in manufacturing and supply circles, and the faithful will simply fall over themselves to beseech and implore you to accept their advertising at empty-steen dollars per page. Then get a cash-register, select a repository for your funds, and employ a secretary who writes a good clear hand to prepare the dividend checks. Oh, yes. One thing more. It is perhaps advisable to provide a little ready money at the start, not too much, of course, say a beggarly million or so, because:

1. It has been known to be somewhat difficult to get the interesting, useful, and instructive matter right at the start.

2. It is also difficult to present it in such an attractive manner as to produce the desired result immediately.

3. It is even more difficult to convince the skeptical Missourianistic public that No. 1 and 2 have been successfully accomplished.

The publisher fills the function of one leg of a three-legged stool, or, since this is an engineering paper, is one angle of a delta-connected three-phase circuit by which mental energy is harnessed for the good of mankind. The other two legs, to revert to the homely simile, are the reader and the advertiser. Picture the toastmaster. "We have with us tonight," orates he, "Mr. Adiabatic Isothermal, who will enlighten us on the subject of his P. D. Q. type R. S. V. P. two-stage belt-driven air-compressors with horizontal intercooler, and plate-outlet valves to the extent of a double-page spread in the advertising section of the 'Mining and Scientific Press'." A toastmaster of less dignity might even say, "Meet Mr. Adiabatic Isothermal", or perhaps even "Shake hands with Ad. Iso.", and remark further, "He is a good scout, so treat him kind". Anyway, the effect is the same. The publisher is the toastmaster, the introducer, so to speak. He renders so valuable a service to the subscriber through the editorial section that said reader pays real honest-to-goodness money for the privilege of reading it; he renders an equally valuable service through the advertising section in bringing to his readers, however remotely they may be situated from the base of supply, the latest news of the development of apparatus and accessories needed by the reader for the conduct of his operations. The advertiser is served through the extension of his sales and the profit accruing therefrom. The

publisher also profits, at least he did before the advent of excess-profit taxes and postal-zone rates for publications, and that is where he comes in. Truly an ideal situation. Three parties, all benefiting from a mutual service rendered each to the others, and yet there are Marxian socialists, bolshevists, and other weird sorts of 'ists who would reform the world by eliminating all profits therefrom.

Perhaps you may conclude from the ending of the above paragraph that the lot of a publisher is one long round of beatific dreams of happy, contented readers, and equally happy and contented advertisers. Don't you believe it! Pause, before you decide to enter the publishing business, because here goes for some real 42-centimetre revelations.

In the first place, editors are born, then made, and the making is a long and tortuous process. There are no ready-made editors lurking coily on the literary shelves waiting to be plucked from their hiding-place in response to Requisition No. 4-11-44 calling for 1 12 doz. asstd. technical editors as per specification herewith and hereby made a part of this agreement. In a paper such as the 'Mining and Scientific Press' you must first catch an engineer of mines, give him years of field experience blended with a predilection for contributing to the technical press and engineering society transactions, then whisk him into an editorial chair and teach him how to cultivate a nose for news, a facility for expression that will not only enable him to use words but say something when he does. Put all these things in a test-tube, bring the mixture to the temperature of fusion, and permit it to cool, then shake well before using. Shake it immediately after using if your subscription list shows a tendency to slump. Then repeat the process ad lib until, after sixty years or so, if your beggarly million holds out, you may have an editor.

Then comes the business staff. That is not simple, either. A good, used business manager, solicitor, or office man is better than a cheap new one. Don't trade in your last year's business staff for a this year's model, however alluring it may be with its shiny nickel, bright new varnish, and luxurious upholstery. Given a sprinkling of common sense, a general business training, an inexhaustible fund of patience, and back it all up with a sincere belief in the worthiness of its cause, a business staff may be recruited from the general rank and file of industry as a whole. With this to start with, all that is needed is time for the development of a real organization. The first hundred years is the hardest, of course. After that, comparatively plain sailing is assured. *Experientia docet*, which means that the business problems incidental to publishing are peculiarly their own, and involve most of the problems encountered in other occupations, plus some new ones, that nothing but concentration, study, and the old gospel of hard unremitting toil will solve.

Consider one angle, that of selling. The hardest job is that of subscription-getting. If cost were ignored it would be easy, and for that matter, so would everything else. The meehanical cost of publishing the 'Mining and Scientific Press' today, that is, paper, postage, printing,

composition, cuts for illustrations, binding, mailing, and wrapping is \$9 per year. The subscription price domestic is \$4 per year. Thus, each subscriber, so far as he individually is concerned, represents a direct monetary loss to the publisher of \$5. If, to pursue this line of thought further, the editorial, executive, and fixed charges are added, the cost becomes \$22 per subscription per year, and the monetary loss to the publisher on each is \$18. And, we may add, costs are getting higher daily. How can this be done? Answer: the advertiser pays the freight.

It is fairly obvious, therefore, that the obligation of the reader to the advertiser is quite as great as to the publisher. The price paid by the advertiser for space produces sufficient revenue to make up this loss, and, if all goes well, leave a crumb or two for the publisher himself. Here then is the selling angle. Each subscriber, considered by himself, represents a direct loss to the publisher, unless that subscriber is a possible—no, probable—purchaser of the apparatus and supplies advertised by the patron of the selling section of the paper. Advertising rates are theoretically based upon the number of buying units represented on the subscription list. Therefore, any subscriber who is not a buying unit means a direct monetary loss to the publisher and the advertiser alike, as mere numbers in a class paper is as useless as the padding of the legs of a grand-opera tenor, good-looking from the surface, perhaps, but a mere sham when exposed to the pitiless investigation of the skilful space-buyer.

The part played by the editorial staff is to prepare and present matter that will hold the interest of the buying units. The business staff must sell this to buying units, and to none other; it must do it at a cost as low as possible, and, when the world is the field, one test of the efficiency of the business staff lies in the cost of selling subscriptions. When it is considered that there are nearly 7000 subscription accounts on the books of the 'Mining and Scientific Press', that the highest amount is \$6 and the lowest \$4, the reader of this little article may amuse himself in calculating the time required to work out a collection system that will get the money for these multitudinous little bills at a cost of a few cents each.

The keystone in the arch, the base of the pyramid, the foundation upon which everything depends is the reader. He is first, and the other two, that is, the advertiser and the publisher, trail obediently after. A publication that has a generous quota of readers, not merely subscribers who are talked or cajoled into taking a paper in order to get rid of an importunate solicitor, who renew their subscriptions year in and year out because they genuinely profit thereby, is as much of an institution as the greatest industrial organization in the land. Any publication that holds the interest of its readers is the advertiser's best bet. An equal interest in the advertisements is automatically assured, for there is no double standard in an intelligently edited paper; the advertising section is as carefully scrutinized as that given over to editorial matter, insofar as is humanly possible; the reliability, honesty, and truthfulness of the advertisements are on a par with every other part of the paper.

Speaking of papers, who was the genius who first spoke of the editorial section as "reading" matter, as if the advertising section were not just as much "reading" matter, if not more so? How, forsooth, does Mr. Mine Manager in the Transvaal, for instance, know that there is such a thing as a new type of air-compressor that has a higher volumetric efficiency than the one he is using and promptly proceeds to buy one to the credit of his sound good sense and the profit of his stockholder? How does he know of an improved stoper, a better ball-mill, a more economical primary breaker, or a more efficient electrical generating set? The ads, that's all.

A mine is a hole in the ground with a—No, why repeat that old one! The first stage is the prospector. In his pack are a pick, a shovel, a pan, and a few sticks of 40% dynamite. Then comes a little hoist, a bucket, some wire-rope, and a car or two. Then with depth, a pump, and perhaps a boiler or gas-engine. Soon a small compressor arrives, with one or two one-man drills, an air-receiver, some drill-steel, and the inevitable belting. The enterprise grows. Candles are no longer adequate. Enter the little electric generator, some lamps, wiring, fittings, and a little toy switchboard. Behold, the prospector departs, and enter the engineer in his lace boots. A bunk-house, a cook-house, and an office go up. The lumber, cement, paint, and corrugated sheet-metal begin to arrive, and, closely following, the mill itself with its multiplicity of auxiliaries. The whole products of the industrial world are represented within its walls; the brain and brawn of thousands are employed in designing and manufacturing the enormous variety of apparatus required in winning the metals from their mother Earth.

How does one know what to buy, and where? Answer: read the ads, and they carefully do, with avidity. How can they help it? From its very inception every mining enterprise is inseparably connected with the advertising section of the technical press. The fund of knowledge of the competent mining engineer is drawn just as much from the advertising as from the editorial section; the two are the gold-dust twins that, hand in hand, lead toward success.

Another thought before the five o'clock whistle blows. Why should the advertiser generously pay so much for his space as to counteract the loss on subscriptions? Answer: what he pays is little, perhaps too little, in view of the value of the service to him. Take the 'Mining and Scientific Press', for example (really, it is the only paper, anyway). For a mere \$45 per week, an advertiser can set forth what he has for sale, and discuss its merits, before an audience of nearly 7000 potential buyers, and do it 52 times per year. The cost of postage alone on 7000 letters is \$140 first-class and \$70 third-class for domestic delivery alone. Sounds fair enough, doesn't it? And yet there is a genius back in Washington who wants to tax advertising as a 'conservation' measure.

Then again, take circular letters. Do you read them? Where may they be found after you have gone through your mail? The waste-basket. And when the 'Mining and Scientific Press' arrives it goes to your desk. When you have read it, it is passed around, frequently through

five or more hands. Perhaps it is clipped in places for your note-book, or it is filed away carefully for binding when the volume is complete. When you want to know who makes what, there is the Buyers' Guide and the Advertisers' Index at your elbow. You pay from \$4 to \$6 per year for this. The advertiser pays an amount depending upon how much space he uses. The publisher gets the remains after the bills are paid.

Everybody is kicking about the H. C. L. and rightly, but—do you realize that the only brake that keeps the H. from getting even H-er, and that, in the end will lick the everlasting stuffin' out of the H, and leave nothing but the C. L., is advertising? Class in elementary economics, stand up. Everybody who knows anything about costs knows that the one great essential cost, and consequently price, reducer is volume of sales. Prime cost is divided into three parts, labor, material, and overhead charges. An increased volume of sales reduces all three, and the last more than the other two. The executive and administrative expense for a Ford automobile, for instance, would be no greater in volume for 200,000 cars than for one. The same applies to every other manufactured article. Before the days of advertising, there were no great manufacturing industries. There were, instead, some odds and ends of jobbing shops, whose output, what there was of it, was limited in distribution to the extent of the transportation facilities of the times and the abilities of the salesmen to get around as best they could and interview personally such prospective buyers as they could reach. Imagine, in contrast, attempting to sell a million safety-razors a year through personal solicitation, and, worse yet, the cost of the safety-razor which had to carry such a selling expense.

In our own field, try and picture to yourself a manufacturer of ball-mills, trying to hire enough salesmen to cover the mining districts of the world and the consequent cost of that same ball-mill. It is the advertisements in the mining papers that do the introducing; again we have the toastmaster in the guise of the advertising section saying "Mr. Mine Manager, meet Mr. Ball-Mill, on page whatever it is in the 'Mining and Scientific Press'." Interested mine managers communicate with the manufacturer of Mr. Ball-Mill, and thus do they get together by the straight-line method, the shortest distance between two points.

The advertising section makes more sales, lower costs, and more profits to reader, advertiser, and to the toastmaster. Therefore, for all of our sakes, buy advertised goods, because:

1. You can thus reduce the cost of what you want not merely to yourself, but to everybody else.
2. You can be reasonably assured that any man who has such faith in himself and what he has for sale as to come boldly out in the open and publish before the world his sales message, is a man who can be relied upon to make good.
3. The advertisers in the 'Mining and Scientific Press' are the flower of the flock. We know this because we picked them ourselves.

Here endeth the lesson.

PROSPECTING IN MALAY STATES

Shall Americans Go Abroad To Mine?

By H. FOSTER BAIN

Anniversaries are times for retrospection, also perhaps for a glance ahead. They are like the high points on the trail where the traveler pauses to look back over the course he has come and then maybe a moment at the way yet to be traversed before the great divide is reached. Ten years ago it was my pleasant privilege, as the then editor of the 'Mining and Scientific Press', to review the progress of mining and metallurgy in the half-century since the 'Press' was founded. Today, no longer in the harness, I may congratulate the present editor and his staff on the secure position in the regard and esteem of the profession held by the 'Press' and on the excellent manner in which it has weathered the storms of the last five years particularly.

In 1910 peace was general throughout the world. The civil war in Mexico, which has distracted the people and almost ruined the country since, only began late in that year. In Europe the cry of wolf had come so often that no one seriously contemplated the world disaster that came so soon after. In America business was excellent. The big new copper producers were making records day by day in production and cost, and mining men were anticipating the finding of many more such deposits. Engineers were busy and happy. Prices were good, and the demand for metals and ores was expanding. Speculation both in New York and London was active.

It is hardly my province to review in detail the history of the years between. Rather I would point to one of the

many contrasts. In 1910 American mining men, both engineers and capitalists, were thinking mainly of American development. There seemed still to be in the United States and its near neighboring countries an ample field for such energy and money as could be spared. Nationally America was still a debtor nation, which meant merely that opportunities were yet so common and so good that it paid to borrow money to invest in local enterprises. Now this has changed. While there is need for much money and labor for home enterprises, the relative position of domestic and foreign fields for investment has been reversed. So much has been said about the increase in America's gold reserve and the gain in liquid resources as compared with other countries, that it is not necessary to labor the point. It is enough to recall the fact that the stock of gold is a burden rather than an asset unless it be profitably employed. It represents something already given in exchange. If either it or the credit that may properly be built upon it lie idle, there is a continuing loss of interest which would soon eat up the profit of the transaction by which the gold was gained. If, on the other hand, the attempt be made by expansion of local credits to put into use in America all of the newly acquired wealth, the result would merely be to set American manufacturers, or operators in other industries, competing against each other for labor and supplies, which would raise costs, and also for markets, which would lower selling prices. In a short time the ad-

vantage of intensified production would have disappeared. Labor, capital, and demand for goods are all bound together by intimate ties and a sudden large expansion of one without corresponding increase in the others unbalances the system. Undoubtedly much money can still be used wisely in America, to improve the transportation system, to develop water-power, to open mines, and to increase plant, but to attempt to employ our whole resources at home, in view of the limited supply of labor, would bring economic disaster by building up costs without corresponding increase of output. American costs are already a handicap in certain directions.

If then we are not to employ our money at home, how is it to be invested? There have been many appeals recently for generous loans to Europe and certainly the need is great. It would nevertheless be a mistake, as Mr. Hepburn has pointed out, to make loans on sentiment. Sound business will be financed without doubt, but our friends abroad should realize that no permanent good can be accomplished by introducing ruin into American finance, and unsound loans would certainly do this. It is also to be remembered that Americans are not by habit a lending people. In 1918 when, apropos of the success of the various Liberty loans, so much was being said of the possible future bond-market in America, I remember discussing the matter with my very shrewd and sound friend, J. H. Mackenzie. Somewhat to my surprise at the moment he took the ground that it might not be an unmixed blessing to develop the saving and bond-buying business in America too generally. As he went on to say, among the reasons for the United States achieving its rapid industrial expansion was not only the wealth of resources but the spirit of the people, the willingness to take a chance which comes from working with your own money. It is characteristic that bankers, who employ other people's capital, cannot and do not make speculative investments. If America as a whole, through growth of the bond-buying habit, converts its private capital into public capital, it is bound to lose something of the venturesomeness that has helped to make the country great. I believe that Mr. Mackenzie is right and that just as the American soldier had to fight according to his own traditions in order to achieve victory, so our financing of foreign investments, to be sound and successful, must be along lines developed in our home enterprises.

Perhaps the greatest difference between American and European mine finance is the much smaller extent to which the former is dependent on public money. In the United States all the big mining groups are controlled by men who are heavy investors in enterprises they direct. In a number of cases the ownership is so closely held that the companies are public in little more than name. In nearly every instance the mine or company was made a success before the public was invited to participate, and the initial risk was run by men who were playing with their own money. This is not true to the same extent abroad. There it is not unusual for a large mining corporation to be managed by men who have little personal financial stake in the enterprise and the initial risk is often underwritten by use of the treasury funds of a

company itself financed out of public money and managed by men who have not themselves put much money into, though they at times manage to take considerable out of, the enterprise. The American system of control results at times in amateur management and rather ruthless disregard of minority shareholders, though I am glad to believe that this latter condition is rapidly disappearing. The foreign system opens the way to all the evils which flow from speculation with other men's money. That it has not oftener led to disaster has been due to the character of the men attracted to the business and the sound self-interest involved in giving good management.

Turning now to the foreign field for mining, it may be asked how this applies and what the opportunities are. Clearly it is not in accordance with American tradition that we should merely buy bonds or shares in enterprises controlled by others. If we put money in, we want not only interest on the money but a share in the profits of development, and, if I understand the American temper, we are willing to take a share in the risk. No mere interest-paying investment is likely to make strong appeal to Americans. It will be remembered that even in our home mining enterprises when public money was called in, it was necessary to offer shares or convertible bonds to secure it. In the past American mining men have contributed technical skill to make successful mines in many lands and have sold machinery to foreign operators. If they are also to furnish capital, clearly they will ask and may justly expect to receive control and a share in the profits over and above return of capital and interest. In other words, the time has come for American companies to go abroad and mine much more generally than they have done in the past, creditable as is the list of important mines in foreign lands of which Americans are either owners or part-owners. There is every reason for pride in the achievements of our people in both metal and non-metal mining. We have developed methods of business and of technology that are distinct contributions to the world's knowledge, and with capital to back our efforts we may fittingly go out to apply these in foreign lands as well as at home.

It is not my purpose here to catalogue specific opportunities abroad. If I am right in the analysis of the situation made above, it will be the business of the leading American mining groups, and such others as may develop, to spend the money necessary to find these opportunities just as in the past they have spent it freely at home, and, when they have made sure of the soundness of the enterprise or have brought it to a stage where the risks can be fairly stated, to invite in such others as may care to take the risk. I may, however, mention some of the difficulties that will have to be overcome, premising that difficulties are but incentives to effort if the reward in view be sufficient.

One of the marked effects of the War has been to revive and stimulate the nationalistic spirit in all countries. A great effort made unselfishly for international peace has resulted in awakening dormant jealousies and reviving national selfishness. We deplore this, but must recognize it in our own national attitude as well as that

of others. It may be argued that the new selfishness is necessary and intelligent. That may be true, but my interest is in the fact that it is here and is one of the factors that must be taken into account in making plans. When the crisis came, nation after nation found itself lacking in some materials essential to successful conduct of the War. This was as true of minerals as of other things. Our own experience with tin, tungsten, manganese, and chrome may be mentioned in illustration. In other lands, as in Australia, the government found itself embarrassed by foreign contracts which controlled the output of war minerals produced under its jurisdiction. This fact has, I believe, been over-exploited and Australia was, I think, fortunate in having had her deposits put into productive condition even though it had been done by foreign capital. The material was there and in usable

sents a temporary phase of opinion and not a permanent conviction. The world's war debt can only be wiped out by intensified production and this requires the fullest development of dormant resources that the widest co-operation can effect.

It is entirely right and proper that each government should keep in closer touch with development than in the past. It must be in position to control its full material resources whenever necessary for its people's good, but this need not require that they be brought into productive condition only by its own citizens. The copper produced by the Arizona Consolidated and the petroleum won by California Oilfields are certainly as much at the service of the American people as though those companies were owned in the United States rather than in Scotland and England; and the same would apply in reverse to Amer-

KALGOORLIE, WESTERN AUSTRALIA

form and as conditions had been in the past this would not have been so if reliance had been exclusively on local capital and technical knowledge. For the present, however, Australians look at matters somewhat differently and are maintaining what amounts to restrictions on the inflow of any foreign capital. However well one may understand the reasons which have led to the development of this spirit there and elsewhere, one can but deplore the growing disposition to put fences around each country and exclude alien brains, money, and energy, regardless of their origin.

Van. H. Manning in his recent address before the American Mining Congress pointed out that if this is to be adopted as the settled policy of the world the United States is probably as well prepared for the resulting competition as any, but, as one American who has lived in and is fond of other countries as well as his own, I prefer to hope that this new national exclusiveness repre-

sent a temporary phase of opinion and not a permanent conviction. The world's war debt can only be wiped out by intensified production and this requires the fullest development of dormant resources that the widest co-operation can effect.

There is another set of conditions which interposes difficulties in many of the independent countries. Generally, if these have attractive undeveloped resources, they do not possess a surplus of capital. They have, however, either been so exploited in the past or have seen other weak nations so exploited, that they are suspicious of all foreigners, and, having passed through a period of loosely granting large concessions to promoters, are now in a reactionary period of extreme reluctance to grant even usual and necessary rights to non-citizens. Siam may be cited as a case in point. This kingdom has suc-

ceeded in maintaining its political independence and is now under an enlightened and modern monarch who is an absolute ruler. Among the heritages of the past is the system of extra-territoriality which enormously complicates the problems of the local government whenever a foreigner is allowed to go into the interior, since he takes his own law with him. Aside from that, it is an affront to the dignity of the nation. The Siamese government has, very properly, made up its mind to get rid of the system and has been pressing the various powers for treaty revision. The British, being close to the country, saw, some years since, the advantages of acceding to the request of the Siamese and gave up their extra-territorial rights in exchange for four provinces, the connecting of the Siamese with the British railways, the appointment of numerous advisers to the Siamese government, and other substantial political and commercial concessions. The Danish government, through the accident of friendship between the King of Denmark and the King of Siam, also gave up extra-territoriality. As a result British and Danish companies have most important advantages in operating in Siam. For example, no American can legally reside more than 50 miles from Bangkok, nor can he legally even go into the interior to look at a property without a special temporary passport, which can only be issued at Bangkok. In the past the Siamese government has not been strict in the enforcement of these regulations, but lately it has shown a disposition to tighten the reins, and the relation between this and the fact that the Senate has never even considered treaty revision with Siam is not hard to see. It will be recalled that Japan only got rid of extra-territoriality by enforcing rigidly the rules against foreigners residing outside the treaty ports. No one probably supposes that the United States has any disposition to be less ready to accord Siam full rights of independence than Great Britain but the latter has acted, even if she did drive a fairly sharp bargain, while we have not. There is no body of informed opinion in America regarding the subject, such as is necessary to bring about any public action in a country which is ruled by public opinion. If there were no law against adultery it would probably require an organized campaign of education to get it put on the statute-books, and this is much more true where it comes to such matters as revision of treaties with small foreign countries with which our relations have so far been mainly those of courtesy. This is one of our handicaps, and if we as mining men expect the United States to play a larger part in world development, we must do our share in building up informed public opinion at home.

Still another difficulty to be met in foreign mining is the fact that in many countries the mining laws and regulations are based upon conditions of the past rather than the present. This is a condition not wholly unknown at home but to an even greater extent it is the general rule abroad. Conditions in the Federated Malay States may be fairly cited here, though there are others which would serve equally well. Tin mining in Malaya was developed by Chinese, who went out into the jungle and opened small placer deposits with simple appliances. There, as

in early gold mining in California, much of the metal was at one time won by hydraulicking, and there, as in California, this was in time curbed because of damage to rivers and farm-lands. As other industries, notably rubber-planting, developed in Malaya, more and more restrictions were placed on mining. These, with the new avenues opened for investment and speculation, have diverted capital until, despite the large areas of possible mining ground remaining unexplored, development has fallen behind and output is steadily decreasing. Meanwhile dredging has been begun with all the resultant demand for central power-stations and yet, so far as I can learn, no relaxation has been made of the old rules designed to give to each mining claim merely the water used on it; nor does there seem to be any adequate recognition of the fact that in modern mining large power-plants are quite as essential as large deposits. This lacuna is even more evident in the new Siamese mining code, which is based upon that of the Federated Malay States.

In Northern Rhodesia the mining regulations have all been framed on the supposition that companies will be floated in London and include provision for a certain portion of the common shares being given to the local government for the mining rights. The possibility of mining to get a supply of metal rather than to float shares is not adequately taken into account, unless there has been recent revision of the rules. In China half the shares must be owned by Chinese, which frequently means that the foreigner must assume all risk and lend his Chinese partners the money they 'invest'. In the Netherlands East Indies the government not only takes an active interest in making geological surveys and mining studies but also develops and operates mines so that the field for foreign capital is, at least at present, limited. In the Union of South Africa there is neither rule nor prejudice against foreign money but there is the competition of well-established houses to take into account. This is a large, but not insuperable, handicap for newcomers. The mining industry is taxed heavily but it is scientifically done and in important matters the government supports and protects the mining companies. Russia is, of course, off the map for the present, though anything is possible there before these lines reach the reader. What will be the policy of the various European powers that have taken mandates over the fragments of the German and Turkish empires remains to be seen, but it will not be surprising if, faced with heavy debts at home, they adopt a narrow policy where it is economically possible.

While the need and the advantages all lie on the side of a larger employment of American capital and technical skill in mining abroad, it will be seen therefore that the field is one only to be entered with circumspection. It requires determination, persistence, and patient accumulation of knowledge. Lest it be thought that my review be too pessimistic I may repeat my declaration of belief that a way can be found even in the countries where conditions are now most discouraging, provided deposits suitable for 'wholesale' mining are present. Clearly it will not pay any American company to go abroad for anything less important.

A GROUP OF COPPER MINERS AT YUSPENSKY

The Spassky and Atbasar Copper Mines in Siberia—I

By J. MACKINTOSH BELL

INTRODUCTION. The sparsely inhabited region occupying the south-eastern portion of the Kirghiz steppes and lying between the headwaters of the Irtysh river and the Syr Daria, in Siberia, is remarkable for the large number of deposits of copper. The most noteworthy of these deposits is that on which is located the Yuspensky mine and those at Djes Kazgan, commonly known as Atbasar. Both these are now the property of the Spassky Copper Mine, Ltd.

The settlement of Spassky is situated 500 miles south-east from Petropavlovsk, on the Trans-Siberian railway.

Here are the smelters for treating the ore from the Yuspensky mine, which is 80 miles farther south-west. The coal mines that provide the requisite fuel are at Karagandy, 25 miles north-west of Spassky. Djes Kazgan is 260 miles west of Yuspensky as indicated on the map.

It is generally supposed that former inhabitants of the steppes, now vaguely described as Kalmucks, carried out primitive mining and smelting operations at the Yuspensky mine. The Russians first began operations about 1847, the two original prospectors being known as Onshakoff and Zotoff. In 1850 these pioneers were joined by

A RUSSIAN WORKMAN

another Russian named Ryasanoff, who soon afterward assumed control of the property and worked it intermittently until 1883. From then until 1897 very little mining was done, although the pumps were kept going intermittently. From 1897 to 1904 Ryasanoff again operated the property. In the last year the Yuspensky mine, together with the smelter at Spassky and other properties, was bought by French and English capitalists and the Spassky Copper Mine company came into being, although several years elapsed before it operated under its own name.

In 1913, the Spassky company, which had already a substantial interest in the Atbasar company, took over the remainder of the shares of the latter concern.

The Spassky Copper Mine company was one of the most remarkable achievements of foreign operations in Russia, notwithstanding quite unusual difficulties attending transport, labor, and climate. The ore from Yuspensky was carried in small native carts drawn by bullocks or camels to Spassky and there smelted with coal brought on a narrow-gauge railway from Karagandy. The copper ingots from the smelter reached the railway at Petropavlovsk in carts or sleds, which on their return journey brought the supplies required at the mines and smelter from the outside world. In winter when blizzards of a fury scarcely known on the American prairie and accompanied by very low temperatures rage across the steppes, the number of drivers, camels, and oxen that perish testify to the difficulties of keeping open the long dreary trail, hundreds of miles in length between the isolated mining settlements and the railway.

The labor was largely Kirghiz. They are a docile people, but capable of being thoroughly unpleasant when roused through an offence against religious prejudice or through a feeling of injustice. The training of these people as miners or workers at the smelter, with the assistance of a far from efficient Russian staff, required a persistence and patience that even the mining engineer, accustomed to pioneer work in outlying districts, is rarely required to show.

Notwithstanding all these obstacles, however, the company prospered greatly from 1910 to 1914; but after the opening of war difficulties arose in connection with the transmission, from London, of the capital required for additional plant; the transportation from England of certain materials in connection therewith; and the mobilization of many of the trained staff for service in the Russian army.

When these difficulties, which were to be expected during the progress of a great war, had been in some measure overcome, matters received a further shock from the outbreak of the revolution. Committees of soldiers and labor deputies were formed at the mines as elsewhere and took practical charge of affairs. The staff, in order to preserve the property from damage, remained and was actually employed by this committee to give the necessary direction to operations. Matters, however, went from bad to worse until finally, notwithstanding the strenuous efforts of the management, the mines and works were nationalized in March 1918. The staff then withdrew,

being given a warm send-off by the employees who had turned Bolshevik. Following the counter-revolution of the Cossacks soon afterward, they returned and were cordially welcomed by the erstwhile Bolsheviks. Operations on a small scale were recommenced and continued until the fall of the Kolehak regime in western Siberia. Mines and works are now once more in the hands of the Bolsheviks.

REGIONAL GEOLOGY. The geology of the Kirghiz steppes shows large areas of monotonous uniformity diversified by others covered by rocks of a great variety of age and petrographic character. Apparently the oldest rocks of the region are quartzites and phyllites, at least some of which are considered to be Devonian. Associated with these are extensive areas of igneous rocks of considerable diversity—porphyries, porphyrites, serpentines—some of which are highly metamorphosed. It is thought that these represent a wide stratigraphic range, but until more ex-

tensive geological work has been done than has so far been possible, no definite relationships can be assigned. Certain of the igneous rocks may, indeed, be later than the earlier members of the great series of Permo-Carboniferous strata, which have a widespread distribution in this region.

Marine Tertiaries cover most of the great desert of western Turkestan, lying south of Djes Kazgan. These extend northward through the depression of Turgai into the northern plains of western Siberia, where they are overlain by fresh-water Tertiary beds and by Pleistocene river and lake deposits.

LOCAL TOPOGRAPHY. Although a distance of 80 miles in a north-east and south-west direction separates the smelter at Spassky from the mine at Yuspensky, there is practically no variation in the character of the topography, which conforms in great part to the character of the geologic structure. The salient features at both localities are the broad plains and the generally low and isolated ridges. From the plains flat-bottomed valleys diverge among the hills and from these valleys again

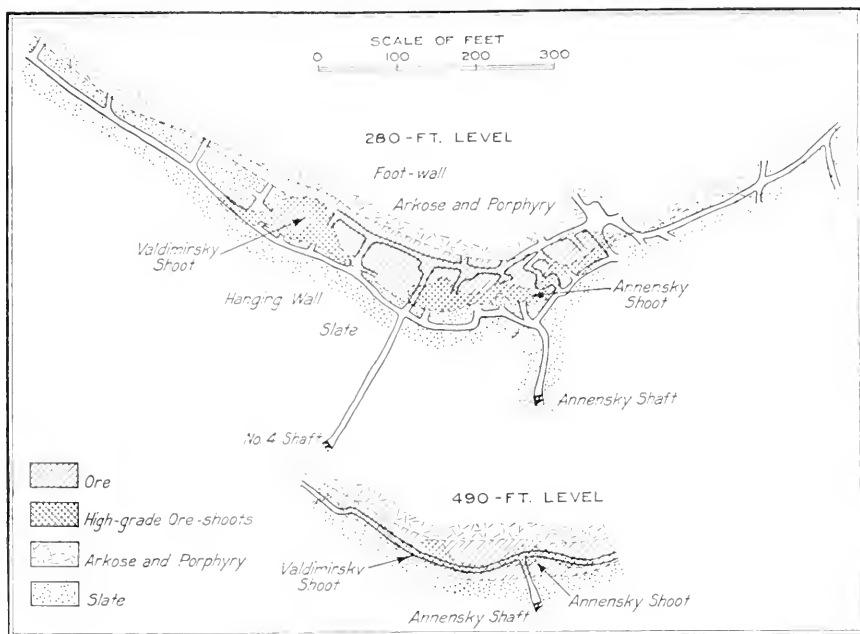

ravines ramify in every direction. Outcrops, often of peculiar and fantastic shape, characterize the crests of the hills and ridges, although in places the debris, so rapidly formed in a dry climate where the variation in temperature is extreme, shroud them to their summits.

The entire absence of trees gives the landscape a dreary aspect, despite the brilliant flora of early summer, which relieves for a time the gloomy picture.

Around Yuspensky the geology is complicated by pronounced faulting, and by the shrouding of important structural contacts by debris. The sedimentary rocks exhibit two phases: a coarse phase, marked by conglomerate, arkose, and grit, none of which shows a definite stratification; and a finer-grained phase, of chert, slate, and lime-

features that need not be described here, lead to the belief that the sedimentaries followed closely after the extrusion of the volcanics and it seems probable that vulcanism may have continued while the sedimentaries were being laid down. The relationship of certain acidie phases of the igneous complex to the sedimentaries in the eastern part of the Yuspensky workings and on the surface above seems to suggest that the igneous rock is here intrusive into the sedimentaries.

THE YUSPENSKY ORE DEPOSIT has a general east and west strike, it bends to northward at both ends and is thus crescentic in form. Its inclination is generally southerly, although in places there is a northerly dip for short distances. It occupies a highly sheared and con-

SKETCH OF THE SPASSKY COPPER MINE

stone. The superposition of the latter over the former shows them in places to be slightly younger, although in general the two types seem to agree in age, the finer-grained rocks being deposited in deep water, whereas the coarser were being laid down close to the margin of an old land. The grits in places contain fossils, which are considered early Upper Carboniferous.

Associated with these sedimentaries are igneous rocks that are mainly volcanic but may be in part intrusive. The following types are represented: quartz-porphyry, oligoclase-porphyry, augite-porphyrite, and hornblende-porphyrite. Both massive and fragmental phases are exhibited, the former being the more conspicuous. There seems no reason to doubt, in view of the fact that the material forming the coarser sedimentaries is entirely derived from the igneous rocks, that the latter are in great part older than the sedimentaries. However, various

siderably faulted zone lying along or close to the contact of coarse-grained massive rocks with highly fissile stratified rocks. The former, the foot-wall country, consist both of igneous rocks and sedimentaries. The igneous rocks are mainly volcanics (older than the sedimentaries) but may be in part intrusive, younger than the volcanics and sedimentaries. The massive sedimentary rocks are fine conglomerates and arkoses. As the primary constituents of both phases of the foot-wall rocks are practically identical and are extremely altered they are often indistinguishable, even under the microscope. Both contain orthoclase, quartz, sericite, chlorite, and pyrite.

The hanging wall of the ore deposit is a slate younger than either of the foot-wall types. This slate is generally dark-gray, in places black and highly carbonaceous, or again calcareous. Adjoining the ore it is almost everywhere greatly shattered.

The deposit is a typical example of a copper-bearing lode, exhibiting in succession downward a zone of surface impoverishment, a zone of oxide enrichment, a zone of sulphide enrichment, and a zone of normal sulphide deposition. It is essentially a highly silicified zone of country containing much quartz and barite impregnated with copper minerals, the impregnation being greatest at or near the hanging wall and decreasing gradually outward into the barren foot-wall. Calcite, galena, and pyrite occur in the non-productive portions of the lode.

The original outcrop of the Yuspensky deposit is said to have been marked only by a few heaps of quartz and barite boulders, stained black, rusty, and green. Development commenced on an insignificant stringer of oxidized copper mineral that gradually improved in quantity and quality downward. Near the surface the copper content was relatively unimportant. At varying distances, but roughly at a horizon of about 200 ft. down, the oxidized ores were largely replaced by sulphides. As the early Russian operators had removed the oxidized ore prior to the mines being taken over by the present company, exact information as to the amount and richness of this ore is not available. However, it is said that exceedingly rich ore was mined beneath the 10 or 15 ft. of impoverished surficial material and above the water-level, which corresponds roughly with the top of the enriched sulphide zone. The poorer oxidized vein-material still visible shows malachite, azurite, cuprite, melaconite, and native copper.

The modern development and success of the mine is entirely due to the phenomenal richness of the ore in the zone of sulphide enrichment. This ore was cut about 200 ft. below the surface and reached maximum strength and richness between 325 and 450 ft. below. At greater depth both the quality and quantity diminished. At about 700 ft. the rich ore is reported to have been exhausted, giving place to the primary vein-filling.

Within the zone of sulphide enrichment there were two distinct ore-shoots, separated by low-grade stuff—the Annensky shoot to the east and the Vladimirskey to the west. The former had a length of over 300 ft. at the 350-ft. level and a width of 45 ft.; the Vladimirskey at the 250-ft. level had a length of 180 ft. and a width of 50 feet.

The copper minerals of these ore-shoots consisted almost entirely of bornite and chalcocite. Chalcocopyrite occurred only in minor amount on the upper levels, but increased in quantity downward. The richness of the ore, especially in the Annensky shoot, was, in places, phenomenal. Thus, between the 350 and 420-ft. levels, there was a well-defined band of almost pure chalcocite along the soft hanging wall so rich that when this part of the ore was being mined it had to be mixed with lower-grade ore for smelting, being richer than the matte desired in the metallurgical process.

These two ore-shoots were found where the enclosing rocks dip southerly, where the hanging wall of slate is highly shattered and where it contains a relatively high carbon content. It is noteworthy that barite was much more conspicuous in the richer ore than quartz or other gangue.

The magnitude of the lode itself is much greater than the shoots it encloses. At the 280-ft. level, for example, it has been proved for 600 ft. and for a maximum width of 70 ft. Other copper-bearing deposits in the same zone of dislocation may be found to represent the continuation of the one described.

As previously mentioned, the richest ore was along the hanging wall and merged outward through increasingly leaner ore into the barren foot-wall country. At Yuspensky no ore was considered high-grade unless it carried approximately 25%; none counted good unless carrying about 15%; while material with less than 8% of copper until recently was thought not worth mining. While the high-grade ore, within the two ore-shoots, has been mostly removed, much lower-grade material extends beyond the high-grade both on strike and dip and passes into the foot-wall. This poorer material is of a grade around 6% or 8% in copper. It seems absurd that this should be styled 'low-grade' ore, but the nature of the deposit and the remoteness of the locality serve to explain the use of the term. Exploration below the 700-ft. level as yet has been inconsiderable. It remains to be seen to what depth the ore of the zone of original deposition persists; the outlook is promising.

The Yuspensky ore contains small quantities of gold and silver, and generally some lead. A typical analysis of rich ore is as follows: copper 19.2%, ferrie oxide 5.2%, lime 0.5%, sulphur 7.8%, barite 34.8%, silica 30.1%, and alumina 2%.

GENESIS OF THE ORE. The material of the Yuspensky lode was deposited in a zone of shearing, in which extensive faulting had taken place, by ascending solutions that apparently belonged to several generations and extended over a considerable period of time. Later changes in the lode, with the attendant shifting of the copper content, were made by descending solutions.

The first process apparently consisted merely in the silicification of the shear-zone close to the contact of the massive and fissile rocks. Shattering of the silicified zone ensued, this being due to renewed movement. In the open spaces thus formed rising solutions later deposited quartz, barite, bornite, and chalcocopyrite to a considerable extent and calcite, pyrite, and galena in minor amount; and at the same time impregnated the wall-rocks, replacing the slate, arkose, and porphyry. Further movement then took place, and it is possible that another deposition of copper-bearing minerals followed, although it is probable that the enriched sulphide zone is due mainly to descending solutions.

The ultimate source of the copper-bearing solutions is not known, but, judging by the widespread occurrence in the locality of small deposits of minerals of this metal associated with shear-zones in the porphyries and porphyrites, it seems probable that the concentration of copper has some connection with these rocks. As indicated in a previous paragraph, these rocks are at least generally older than the slates and arkoses forming the principal wall-rocks of the Yuspensky deposit, though not much more so, and it is possible that certain of them, difficult,

owing to petrological similarity, to differentiate from the main igneous mass, may be actually younger.

While part of the rich sulphide ore close to the hanging wall in the zone of sulphide enrichment may be due to a second generation of ascending solutions, it is thought that the principal portion of the copper of this zone was derived from the oxidation of the original copper-bearing minerals above, the copper derived therefrom being carried downward in solution as sulphate and deposited as sulphide below the water-level. Either original sulphide or the carbon content of the hanging wall was responsible for the precipitation.

METHODS OF MINING AND TREATMENT. The first mining was by an open-cut. Later the ore was brought to the surface through a number of small shafts worked with the simplest equipment. When the property was acquired by the present owners more systematic development began, but, owing to the remoteness of the locality, it has often been necessary to resort to devices and methods that would be considered primitive elsewhere. There are two principal shafts and a number of minor ones connecting the workings with the surface, levels being opened therefrom at intervals of 10 sagues (70 ft.), namely, at 280 ft., 350 ft., 420 ft., 490 ft., 560 ft., 630 ft., and 700 feet.

The principal difficulty encountered in sub-surface development has been in connection with the highly crushed hanging-wall slate. Drifts, winzes, raises, and cross-cuts in or near this wall required the strongest timber, which had to be brought many miles across the steppe, and needed frequent renewal. The mining method adopted was to extend a drift along the hanging-wall side of the vein, closely timbering it against the fissile slate; every precaution in blasting being taken not to shatter the latter. When this drift had been completed for the length of the orebody, and cross-cuts extended to the foot-wall at the desired intervals, a second slice of ore was removed immediately adjoining the drift, and so on, slice by slice, until the whole of the orebody at the level had been taken out. Waste was filled in after each successive slice, the quantity of timber as preliminary support diminishing toward the foot-wall. After the ore at the level had been all removed, the slice-and-fill system was continued upward.

The ore from Yuspensky was assembled in stock-piles at Spassky together with coal from Karagandy and limestone flux from the country adjoining Spassky. Smelting was at first done in small and primitive blast-furnaces, which required constant re-building, the materials of construction being mostly manufactured locally. When the present company commenced operations much reconstruction of these furnaces was necessary and in 1908 only one furnace was available, with a capacity of about 200 tons of copper monthly. In time new furnaces, still, however, on Russian lines and not water-jacketed, were constructed and the complement of converters correspondingly increased bringing the capacity of the plant in 1912 up to a little more than 400 tons monthly. The converters first erected were subsequently replaced by Pierce-Smith basic-lined kettles.

When it became apparent that the rich ore would soon be exhausted, a concentrating plant, using the Minerals Separation flotation process, was erected at Sara Su, to treat lower-grade ores and a reverberatory furnace was built at Spassky to smelt the concentrate therefrom.

Construction on both these units was delayed by the outbreak of war and neither was really effectively in use when the troubles attending the revolution began. The plant at Sara Su was destroyed by fire in July 1919.

STATISTICS. Some idea of the richness of the Yuspensky ore-shoots is gained from the value of the ore raised in the few years preceding the War. Thus, for the year ending September 30, 1909, 15,551 tons of ore was lifted containing an average of 16.6% copper; for the next twelve months 12,581 tons averaging 19.2%; and for the next 31,302 tons containing 15% copper. In the 15 months ending December 31, 1913, 43,591 tons of ore was raised averaging 22% copper, and in the year 1914, 20,697 tons with 20% copper.

The production of metallic copper since 1907 to the end of 1914 has been as follows:

For year ending	Tons
September 30, 1908	1322
" " 1909	1641
" " 1910	2384
" " 1911	2858
" " 1912	3998
December 31, 1913	*6251
" " 1914	4683
*15 months.	

The cost of production has been exceedingly high compared with operations in other regions but it has been relatively low considering the remoteness of the locality, the several establishments, and the various other difficulties previously mentioned against which the company has had to contend. In the year ending September 30, 1908, the cost of production of a ton of copper is reported to have amounted to £41, but was actually more; for the year ending September 30, 1911, £37 14s.; and for the next 12 months £28 9s.—a relatively low figure, which seems approximately to have been maintained till the blast-furnaces were closed in December 1914.

Notwithstanding the high cost of production the company made handsome profits in the five years preceding 1915, being partly assisted in this regard by the higher price prevailing in Russia for copper (owing to the import duty) than elsewhere in Europe. Thus, in the year ending September 30, 1911, £77,000 was distributed in dividends, or 17½% on the capital, which then stood at £600,000; while in the following year dividends amounting to 25% on the capital were paid. In the 15 months ending December 31, 1913, the dividends amounted to rather more than 25% on the capital, and in 1914, when the capitalization had risen, owing to the inclusion of Atbasar, to £1,000,000 (with issued £1 shares amounting to £979,840) 10% was paid.

The ore-reserve at the end of 1915 is given as 429,475 tons, averaging 7.8% copper, which may be compared with 6100 tons of 20% ore in the mine, 21,083 tons of 20% ore in dumps, and 346,917 tons of 7% ore in the mine at the end of 1914.

The Prospector

By JACK MULHOLLAND

*The prospector is the man who is directly responsible for the large production of metals from the numerous mines which are in operation today. Most of the mines of the world have been found by the hardy pioneer; and only those who have been actually interested in this kind of work can realize to the full extent what hardships and privations must be endured if the prospector wishes to succeed. Take, for instance, the rough precipitous ranges of the Western States or the Province of British Columbia. Every pound of provisions and the necessary equipment, bedding, etc., must be carried on his back, though in many places it would seem impossible to be able to navigate without any burden; but those obstacles are overcome, and when night overtakes him, and lying on his bed of boughs before a roaring camp-fire with a good substantial pipe of tobacco, the prospector is generally the most contented and happiest man in the world. A few years ago there were a large number of these men roaming around in various districts, and, in fact, nearly all of our producing mines were found at that time. Although there are a large number of new shippers on our list, on investigating we find that they are old locations now being newly developed, thanks to the advanced price of metals and the great demand for them during the war period. A good many of the old class of prospectors have cashed in and crossed the divide, but there are still quite a few left, and the majority of those have quit and are seeking an easier means of getting their livelihood.

What provision has been made for the ones who have failed to find the so-called bonanza? A few years ago it was a common occurrence and an easy matter to find a business-man who would grubstake a prospector; yet today I doubt if you could find one in a thousand who would be willing to give back a small amount of what he has gained from this great developed industry. The Provincial government of British Columbia has decided to grant a large sum of money to aid the returned soldier and assist him financially to prospect. This may be the means of making a few more discoveries. Let us hope that it does. But it is funny that they never thought of spending a little of that money on the genuine prospector, the man who already had ten or fifteen years hard-earned experience and was forced to quit the game for lack of support. These same men are the country's greatest asset and should be helped, and the necessary means should be provided to keep them in the hills. If this were done it might create an incentive, or awake an interest in the generation growing up. It would at least be easier to induce them to get in and take hold and continue the work where the old-timer leaves off. The young men of today are just as good as the old pioneer was at their time of life, but the ambition for that kind of work has been killed, and the public in general is to blame for it. You

will find in every part of the country men who are old and feeble, poorly clad, and in many cases getting barely enough food to keep them alive. Those men are the ones who produced the great mineral wealth which you so often boast about, and of which you see an evidence here today—and yet, you wonder why the growing generation does not get in and follow in that same old-timer's footsteps. The life of a mine is limited, and to keep up the supply of metals to be able to fill the great demand, new mines must be found.

Another point which must not be lost sight of, and one which is vital, is the new discovery. There are only rare exceptions where the surface croppings are rich enough to allow the prospector to take out and ship enough to pay development expenses; and even in such a particular instance, there is no trail or means of transportation, therefore capital is needed. What invariably happens is this: the prospector being unable to obtain assistance, does the necessary work to fulfill the requirements of the law, and consequently the property lies practically idle for many years.

There are hundreds of this kind of group throughout the North-West, and with an expenditure of sometimes a small amount of money, a good many of those same prospects would become producing mines. What I consider one of the most essential needs of the present day is small development syndicates. This in my estimation is one of the greatest money-making schemes. For instance, options could be obtained on two or more promising prospects, for the purpose of developing them so that they would be considered in fit shape to turn over to the larger mining corporations, who are nearly always looking for a developed prospect. This would be a snap for business men who are well able to put up a few thousand dollars apiece; and by employing a good, practical, and competent man to handle and take charge of the work, the possibility of failures would be eliminated.

Prospecting in the developed or more settled regions is far more expensive for the present-day prospector. The higher altitude where the formation was practically exposed was examined in most places by the old-timer, who naturally looked for minerals in the places where they were easiest found. The lower altitude, which is generally covered by deep wash and heavy timber, has to be prospected by pick and shovel, which means time and labor and is very often disappointing. There are a good many ways and means of assisting and encouraging the prospector, and there should also be a free system of schooling through the winter months. Literature on practical mineralogy and geology should be published in a more simple form for the purpose of assisting the beginner. All the present literature, some of which is called 'prospector's handbooks', is utterly useless, unless the prospector should happen to be a college graduate. It always seemed to me that those books were written by professional men who knew but little on the subject, but by using such jaw-breaking and fictitious names they expected the general public to give them credit for being mining wizards.

*An address delivered before the International Mining Convention at Seattle on April 8.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

COLORADO

MUCH MANGANESE ORE BEING MINED AT LEADVILLE.

LEADVILLE.—With the disappearance of snow, mining activity, handicapped for fully four months, is reviving. Already half a dozen manganese producers are again on the shipping list and with the market re-opened a heavy tonnage will be mined and shipped this summer. Lessees are planning an active season in various sections, more especially on Carbonate, Fryer, and Iron hills; the Sugar Loaf, East Tennessee, and Iowa Gulch sections; and Canterbury hill.

Work is to be resumed shortly on the Emma and Marble placer on East Tennessee and the National Mining Co. is awaiting the opening of roads to get to work on Iowa Gulch properties secured from A. S. Sharp during the winter. In the Canterbury Hill section the Prospect Mountain Tunnel Co. will extend the tunnel projected to cross-cut the formation in territory heretofore unexplored. At present few of the larger companies are operating, but the Yak, Ibex, and Down Town mines are shipping steadily, while lessees are adding their quota to the district's production.

BRECKENRIDGE.—Rich lead-carbonate ore has been opened by Nels Ostrum and associates in the main tunnel of the Iron Mask on Schock hill. The Iron Mask company is extending a drift on the main vein at the 100-ft. level and is mining a good grade of ore. Detwiler brothers and Briback are sinking on the Price lode to open new stoping ground. The Foremost property on Chief mountain, that last year produced high-grade lead-silver ore, is again active with lessees operating. The Tonopah Placers Co. is operating a churn-drill ahead of its dredge, below Breckenridge; other boats have also started operation.

TELLURIDE.—Shipments of concentrates from the Tomboy and Smuggler Union mills for April were heavier than for several months, amounting to 130 cars, 70 from the Tomboy and 60 from Smuggler Union. The Liberty Bell mill resumed treatment the first of the week. New orebodies have been developed during the winter and a large tonnage of ore is reported available for milling.

CHAFFEE COUNTY.—The Colorado Silver Mines Co. owning a large acreage on Shavano mountain in the Chalk Creek mining district, near the town of Romley, plans construction of a concentrating plant. Test shipments, to the Ohio & Colorado smelter at Salida, of milling and sorted ores from the shoot in the Ada Bell vein, gave returns of \$12.13 per ton for mill grade and \$24.40

for sorted ore, based on silver at \$1 per ounce. One lot gave smelter returns of 50 oz. silver in addition to some gold, lead, and zinc. The property of the company is on the opposite slope of the mountain from the Mary Murphy mine, that has a production record exceeding \$25,000,000 and is still producing.

MICHIGAN

SHIPMENTS OF COPPER INCREASE.

HOGHTON.—The first shipments of copper by boat left last week. The Calumet & Hecla has a considerable quantity awaiting shipment. While the output is now less than the shipments that are being made by rail, a considerable portion of the winter's accumulations still awaits transportation. Of the 32,000,000 lb. that the Calumet & Hecla company carried at the first of the year, more than 70% has been sold and contracted for. Much of the accumulation at the Hubbell dock is for foreign shipment and will go out within ten days. At Dollar Bay there is approximately 10,000,000 lb. Recent shipments are averaging six cars per day from the Hubbell plant, which now handles all of the production of the Calumet & Hecla and allied corporations. Indicative of the European demand for copper it may be stated that half a million pounds per day of the total shipments from the Lake Superior district is going to France and Belgium. This is being rushed to New York for trans-shipment instead of waiting for the cheaper and slower boat transportation.

In connection with the computations on the production of the Champion mine of the Copper Range group it must be remembered that, while there is a falling off in the output of 'rock', the mine never was sending so much mass copper to the smelter direct as at the present time. The average now is two cars per week of practically pure slab-copper; this does not show in the shipments of rock.

Tamarack shaft No. 5 of the Calumet & Hecla is bottomed at the 40th level. The shaft is used only for hauling purposes. It handles 9000 gallons in the large bailers that are used, so that 3,000,000 gallons per day is being taken out. Practically all the water is drained into this shaft. When the new underground haulage-way is completed it will be possible to re-open the Tamarack No. 5 for mining again, inasmuch as No. 12, South Hecla, will drain the whole district and the water will be handled by five electric pumps. When actual conglomerate-lode mining at No. 5 shaft was suspended the

openings all were in fair ground. This territory will be handled by sub-shafts. No. 3 Tamarack now is producing 9000 tons per month. There has been no sinking there for two years, but 23 drilling-machines are working. Work on the haulage tramway continues. Ultimately, when the present plan for hoisting the remaining conglomerate ore through the Red Jacket shaft is completed the whole line of shaft-houses at the Hecla, with the exception of No. 12, the supply shaft, and the shaft for the electric-wire service, will be taken down. The haulage connections holed to No. 6 and No. 7 three months ago. Additional electric power will be supplied from the new turbines ordered for the plant at Lake Linden. There will be two additional high-power turbines to replace the low-pressure equipment now in use. The latter will be kept for auxiliary purposes. It is hoped to have the new turbines ready for operation next fall. That will increase the electric capacity by 60,000 kw., according to plan.

NEVADA

NEW CONSOLIDATION AT GOLDFIELD.

GOLDFIELD.—The Atlanta, Merger, Blue Bull, C. O. D., and several other companies have passed into the control of H. G. McMahon and A. I. D'Arcy of the Goldfield Development Co. D'Arcy and McMahon have consolidated the companies under the name of the Goldfield Deep Mines Co., incorporated for \$750,000, or 15,000,000 shares of a par value of five cents. The company plans to prospect by drilling and then sink a 3000-ft. shaft to the granite in the eastern part of the district. Prospecting of the Consolidated vein in the granite has been proposed several times, but the expense can be met only by a combination of several assessable companies, using their treasuries jointly for the sinking of one shaft. D'Arcy and McMahon now control all but seven of the well-known Goldfield companies and the future of the district largely is in their hands. The Development again has reported that the mill is to be started, this time early in June. One hundred tons is to be treated daily. The returns from assessment No. 1 have been good, the delinquent list amounting to only 150,000 shares. It is estimated that the amount received will place in the treasury \$75,000, against which there is an indebtedness of \$36,000. It is reported that much of the ore on which the mill will be started will come from the Silver Pick, where there is a good tonnage of ideal material.

SILVERTON.—The new owners of the Tognoni group are erecting machinery to continue sinking the shaft from the present depth of 60 to 200 ft. and an effort is being made to finance the construction of a small mill. The finding of rich ore near the surface has led many lessees to start work. Engineers who have expressed poor opinions of other Nevada silver districts comment favorably on Silverton. Ore has been shipped at intervals since 1870, practically all coming from shallow shafts. The formation is limestone, greatly faulted, and intruded by rhyolite. There are three main veins and many cross-fissures, the vein in which the shaft is being sunk having

a width of more than 25 ft. For the last 30 ft. the shaft has been in ore, much of which is of high shipping grade.

TOKOR.—The Mt. Vernon Mining & Milling Co. plans to erect a small mill to treat 15,000 to 20,000 tons of \$15 gold-silver ore in claims bought from the Le Champ-D'Or French Mining Co. These claims have been worked at intervals since 1895, mainly by the French company. Shallow shafts have been sunk and a 500-ft. cross-cut tunnel, driven by the Le Champ-D'Or, reaches a depth of 150 ft. The Mt. Vernon for several months has been prospecting to find a shaft-site. The veins, four of which are exposed in the tunnel, are from a few inches to eight feet wide.

MINA.—The Minerals Separation engineers have reported to the Simon Silver-Lead company that the use of the Minerals Separation process will give an extraction from the sulphide ore of 93.9% of the silver, 93.7% of the lead, and 71.3% of the zinc. The silver-lead concentrate is valued at \$126 and the zinc at \$39, the former containing 76.1% of the silver saved and the latter the remaining 17.8%. The annual report of the Simon estimates the ore-reserves at 400,000 tons and states that "this ore is of such a grade as will return \$7.20 per ton net profit at the prevailing market prices for the contained minerals". P. A. Simon, president and general manager, says in the report: "It should be noted that our estimate takes into consideration the metallurgical treatment and losses, which are now definitely known." The report of the Minerals Separation is the first statement of the Simon Silver-Lead giving details of the result of tests on the ore.

UTAH

COL. WALL OPTIONS STOCK IN DALY MINING CO.

ALTA.—Excellent progress has been made in the watering of the Emma mine, and diamond-drilling has been started. Recently the showing on the 100-ft. level has improved. This ore, which a short time ago pinched down to one foot, has now widened to the full width of the face. Drilling from a four-foot hole on the right-hand side of the face assayed 15 oz. silver and 26% lead, according to George H. Dern, general manager.

PARK CITY.—Shipments of ore for the week ended May 8 totaled 2272 tons, as compared with 2803 tons for the previous week. The Judge M. & S. Co. shipped 629 tons; the Silver King Coalition, 723 tons; Ontario, 194 tons; Daly West, 296 tons; and Daly Mining, 52 tons. The Judge smelter shipped a carload of 33 tons of premium spelter during the week.

Announcement of the consummation of a mining transaction involving between \$300,000 and \$400,000 has been made by George W. Lambourne, general manager for the Judge Mining & Smelting Co. By an agreement recently made Mr. Lambourne has acquired an option on Col. E. A. Wall's interest in the Daly Mining Co., which amounts to between 90,000 and 100,000 of a total capitalization of 150,000 shares. The property of the Daly Mining Co. lies between the Ontario and the Daly-West mines, and has produced in excess of \$10,000,000 worth

of ore, with a dividend record of \$3,000,000. The future is considered promising, according to Mr. Lambourne, as there is a large virgin territory to prospect, in addition to ground already developed. The ore produced in the past has been silver-lead, with the silver content frequently running as high as 100 oz. per ton. The Daly Mining Co. also owns a half interest in the lower Ontario drain-tunnel and an interest in the upper Ontario drain-tunnel, in addition to a coal mine at Coalville, near here. Mr. Lambourne will leave within a few days for New York, where the financial details will be settled. It is more than likely that the option on Col. Wall's holdings in the Daly will be taken over by the Park-Utah Mining Co., development work in this latter property being carried on through the lower Ontario drain-tunnel. The physical condition of the Park-Utah is excellent, as ore has been opened up in four places and the lower tunnel is being put in shape for transportation of ore and supplies. When Col. Wall took over the Daly, some seven or eight years ago, it was believed at the time that the property was worked out. By patient work he brought the mine back to life and showed that there is still a large amount of undeveloped but promising ground.

EUREKA.—Ore shipments from the Tintic district for the week ending May 8 were the largest for many months, a total of 180 cars having been sent out, as compared with 124 for the previous week. The Chief Consolidated shipped 58 cars; Tintic Standard, 22; Dragon, 20; Eagle & Blue Bell, 15; Iron Blossom, 14; Colorado, 13; Grand Central, 8; Mammoth, 7; Victoria, 6; Centennial Eureka, 5; Iron King, 3; Gemini, 3; Bullion Beek, 2; Alaska 2; Sunbeam, 1; Swansea, 1.

The May Day drift, leading from the 1800-ft. level of the Yankee shaft, has entered favorable territory, according to George H. Dern, general manager. The drift is now 800 ft. from the shaft, and after cutting through a thin porphyry dike, recently broke into a fissure in a dolomite limestone formation. The main objective of this drift is another fissure about 300 or 400 ft. ahead, as it was in this latter fissure that the ore was originally followed from the 700 to the 1100-ft. level.

At the Phutus mine, adjoining the Chief Consolidated, the shaft has reached a depth of 1650 ft. The present plan is to sink to the water-level before prospecting, and from all indications it will probably be the middle of June

before this can be accomplished. Craig Sandusky is now superintendent of the property, having succeeded W. McClain, who has taken a lease on several properties in another part of the district.

A petition has been circulated among the members of the Salt Lake Mining Exchange asking the Board of Governors to appropriate \$250 to help defray the expense of compiling and publishing an up-to-date map of this district, to aid in a publicity campaign. It is expected that a decision will be forthcoming promptly.

The Chief Consolidated Mining Co. has just paid its 24th dividend in the amount of 10c. per share, or a total of \$88,423. The grand total of such disbursements to date is \$1,694,471. The Chief Consolidated has sold its build-

THE EUREKA-LILY MINE, IN THE TINTIC DISTRICT, UTAH

ings at Homansville, consisting of a large boarding house, compressor building, lodging houses, etc., to the Griggs Huish Leasing Co. The buildings are now being dismantled and will be re-erected in the vicinity of the compressor-building, lodging houses, etc., to the Griggs company.

BRITISH COLUMBIA

DIAMOND-DRILLING IN PORTLAND CANAL DISTRICT.

TRAIL.—To supply the new concentrator to be built here the Consolidated Mining & Smelting Co. of Canada is constructing a pumping-plant possessing some novel features. In order to be at the required distance from the water in the Columbia river at its lowest stage, and to avoid being flooded at high water, the plant is being housed in a waterproof, solid concrete chamber approached by a waterproof sloping tunnel also of concrete. The tunnel portal is well above high-water mark.

VICTORIA. Charles Camsell, manager of the Vancouver office of the Canadian Geological Survey, has made the following tentative assignments for work during the coming season: Cariboo, D. A. Nicholls; Coquihalla, G. E. Cairnes; Eutsuk lake, R. W. Brock and F. S. Falconer; Frasa delta, W. A. Johnston and A. C. Shephard; Lardeau, M. F. Baneroff; Peace river, E. H. McLearn; Salmon river, S. J. Schofield; Taseko iron deposit, J. D. Mackenzie and C. H. Freeman; west coast of Vancouver Island, V. Dolmage.

The Tidewater Copper Co., at Sidney Inlet, Vancouver Island, has developed water-power on Indian creek and has re-started its concentrator at the Indian Chief mine. About 1000 tons of ore has been run through the mill, and the flotation process is said to be working smoothly.

PRINCE RUPERT.—The Granby Consolidated M. S. & P. Co. has effected the sale of \$2,500,000 worth of 8% bonds. This money is required to finance improvements that have been made at the Anyox smelter, including the by-product coke-ovens, and part of the equipment and development of the company's Cassidy colliery. It had been the intention to finance these improvements out of profits, but the unsatisfactory condition of the copper market and labor conditions prevented. P. Olesen has bonded a group of 16 claims from W. Hanna and Charles Flood at Hidden Creek, adjoining the Granby company's holdings. The consideration is stated to have been \$700,000. Boyle Brothers, of Spokane, have been given a contract for 12,000 ft. of diamond-drilling at the Big Missouri and another contract for drilling at the Premier mine. Lynch Brothers, of Seattle, have been given a contract for drilling at the Spider and Northern Light groups for the Anglonian Syndicate. The new compressor at the Spider has been put in place.

The last shipments of heavy machinery for the concentrator at the Premier mine have been delivered at the mine and the work of erection has been started under the superintendence of engineers from the A. S. & R. Co. The mill will have a capacity of 100 tons per day. Another shipment of about 300 tons has been taken from the mine to the wharf at Stewart, but the strike of the steamship-hands on the Grand Trunk Pacific boats will delay shipment to Tacoma. The steamship strike, too, is causing considerable inconvenience to mining men wishing to go to or come from Stewart, the town being temporarily cut off from communication.

HEMLEY.—A dispute between the employees and the management of the Hedley Gold Mining Co. regarding wages has been settled, the former receiving an increase of fifty cents per day. The minimum wage paid in the mine now is \$5 per day. G. P. Jones, the manager, states that it is not certain that the property will be able to operate at a profit under these conditions, but he was willing to give it a trial.

STOCCAN.—Metal mining in the district is tied up by a strike of the miners, who are demanding an increase of one dollar per day in wages. As a result one of the richest silver-producing camps of western Canada has become inactive for an indefinite period.

ONTARIO

SHORTAGE OF LABOR AT COBALT.

TORONTO.—The project for building a railway from Elk Lake to Gowganda will be carried out on a more extensive scale than originally proposed. The Canadian Light Railway Construction Co. has secured a charter from the Legislature, which only requires the formal assent of the Lieutenant Governor to become law. It has already an engineer and staff at work laying out the route to Gowganda and is ready to begin construction at once. In addition to serving Gowganda, a line will be built eastward from Swastika to Kirkland Lake, thence turning southward to Larder Lake and Skead Township and connecting with the Tensikaming & Northern Ontario line at Boston Creek. A westward extension into West Shining Tree and a branch to the Matachewan gold district may be undertaken later. The announcement has created great satisfaction in mining circles and will stimulate operations in localities that have been long retarded by a lack of transportation facilities.

KIRKLAND LAKE.—May 20 is the time officially set for the resumption of mining operations at the Tough-Oakes and the mill is expected to be running in the earlier part of July. Official announcement is also made that the merger of the Tough-Oakes and the Aladdin Cobalt has been completed and that the Burnside will be consolidated with these properties on May 10. The ore now in sight in the Tough-Oakes and Burnside mines is estimated at between 17,000 and 18,000 tons, which is stated to assay \$12 per ton. The Hutton-Kirkland is to be reopened immediately, the capital necessary to finance extensive development having been secured. H. M. Porteous, former manager of the Vipond-North Thompson, has been appointed manager. Arrangements are being made to secure power from the Northern Ontario Light & Power Company.

PORT ARTHUR.—D. C. Peacock, of Duluth, and J. D. Lamont, of Virginia, mining engineers, are making a survey of the old Silver Islet mine 30 miles from Port Arthur with a view to reopening it. The Silver Islet, which was in operation 50 years ago, was a notable producer yielding about \$3,000,000 of silver, but was abandoned owing to flooding by the waters of Lake Superior. The estimated cost of pumping out the mine is \$50,000, but it is thought that a modern hydraulic equipment will overcome all difficulties from water. The shaft is 1200 ft. deep and hundreds of tons of rich ore were in sight when the mine closed down.

COBALT.—The tendency to hoard silver against declining quotations continued during the first ten days of May, and the consensus of opinion, despite the slump, appears to be that higher prices will again be realized. The Nipissing Mining Co., Canada's largest silver producer, has not shipped bullion for several weeks, although production is being maintained at an average of about \$375,000 monthly, or more than \$1,500,000 for the first four months of the year.

THE MINING SUMMARY

ARIZONA

Jerome.—The United Verde Extension company, in development work during the past few months, has entered the orebody on the 1500-ft. level and has run about 560 ft. of cross-cuts and drifts. The ore on the lower level has not come up to the tenor of that on those above, averaging but 5%. The management, however, does not regard this as discouraging, although somewhat disappointing. The orebody has not yet been entered on the 1600-ft. level, but this

Mining Co. will be made before Judge Deltrich in the United States district court at Coeur d'Alene on May 31, when the Federal company will renew its application for an order permitting it to make a raise from the underground workings of the Hecla to the surface as a means of establishing its apex contention. This hearing was to have been held recently at Moscow, where the Federal Court was in session, but by stipulation between the attorneys, A. H. Featherstone for the Federal company and John P. Gray for the

DREDGING IN THE YUKON

should take place soon. Verde Extension had on hand at the first of April 23,857,634 lb. of copper. It will increase output soon but not to full capacity.

COLORADO

Mayday.—W. A. Becker, who is having a cross-cut driven at the Little La Plata, intends to start sinking in one of the old tunnels on the Little La Plata where some good ore was mined a number of years ago.—Moigg & Curtet, lessees on the Southern Boy, expect to cut the vein with any round now. They are running a cross-cut to get under a rich ore-shoot in a shaft.—The Jumbo Mining Co. has started a force of men to work in the Cunningham tunnel, which, it is said, they will extend 500 ft.—Paul Dalpra, who has been leasing on a block of the Jumbo, will start shipping as soon as the railroad spur is opened to Mayday.

IDAHO

Coeur d'Alene.—Another move in the apex litigation between the Federal Mining & Smelting Co. and the Hecla

company, it was transferred to Coeur d'Alene on the date stated. Last April Judge Deltrich denied a similar application, but he has granted a further hearing.

MISSOURI

Joplin.—The Louisiana Mining Co. is developing what promises to be a good mine on the Rensenhouser land on the south side of Shoal creek, several miles south-west of Joplin, near the Fillmore bridge. The company has been opening the ground for some time, running three drifts from the mill-shaft. The 150-ton mill on the property is being operated part time, most of the work being devoted to underground development.

MONTANA

Butte.—As a result of a meeting of the I. W. W. miners' union, the recent strike has officially ended. All members were urged to "strike on the job". Simultaneously with this order, the following notice was posted at all of the mines: "No member of the I. W. W. will be employed at this prop-

erty. This action is an attempt to completely expel the radical element from the Butte district. This order will be enforced even at the expense of stopping operations. The High Ore and Mountain Con mines have already been shut-down. Other A. C. M. properties no doubt will follow suit. During the month of April, 25,000 tons of ore was milled at the Butte & Superior concentrator. Six thousand tons of concentrate yielded 6,300,000 lb. of zinc and 113,000 oz. of silver.

Whitehall. The Jefferson Mines Co. is operating the Lamplight claim. A 40-ft. winze sunk in the prospecting tunnel cut ore assaying \$32 per ton in gold, silver, and copper. This vein is believed to be an extension of the ore-body developed in the adjoining Dorothy property. Cross-cuts have been driven from the bottom of the winze, and drifting to the north will continue for a distance of 50 ft. H. G. Klenze is principal owner of the property.

NEVADA

Carson City.—Ore panning free gold has been entered in the shaft sunk at the Southwest Comstock Extension, in the North Carson section of the Comstock Silver Belt. The shoot is said to have widened to three feet with the shaft apparently entering an orebody. Thurman G. Roberts is manager. The erection of a head-frame is proceeding at the property of the Nevada Protective Mining & Investment Co. and sinking of the shaft with power-drills will start about May 30. The shaft is 70 ft. deep and will be sunk at least 400 ft. Equipment includes a hoist and compressor. E. R. Argersinger is manager.

Golconda.—Rich silver ore has been uncovered one mile north of the Pinson ranch, close to the Southern Pacific and Western Pacific railroads. The strike was made by George Blaine and S. B. Kasper of Golconda and a strong vein is said to be exposed.

Manhattan.—The drift from the 800-ft. level of the White Caps has advanced on the vein 210 ft. The vein is 22 ft. wide and is said to average \$25 in gold per ton. The Black Mammoth Co. has purchased a 50-hp. electric hoist and a two-drill compressor. Sinking is to be resumed as soon as machinery is in place.

Winnemucca.—The Nevada Harmony Co. is erecting a hoist, compressor, and pump preliminary to sending the 100-ft. shaft 200 ft. deeper. A station will be cut on the 300-ft. level and drifting started. Ore of fair grade is being developed at the 100-ft. point. G. P. Williams is superintendent.

BRITISH COLUMBIA

An offer of settlement was made on May 12 by the Dolly Varden Mines Co., of Chicago, to the Taylor Mining Co., which the latter accepted. The Dolly Varden company has withdrawn all legal proceedings, together with the last petition for disallowance of the second legislative Act bearing upon the controversy, so that the Taylor Mining Co. is now in undisputed possession of, and with a statutory title to, the Dolly Varden property.

Victoria.—Through agreement finally reached with the Dominion and provincial governments in Canada the Granby Consolidated Copper Mining, Smelting & Power Co. has paid during the past few months close to \$1,000,000 in back taxes.

YUKON TERRITORY

Dawson.—The ice has broken in the Yukon and the entire river will soon be open for navigation. A considerable influx of miners and prospectors is expected to the Mayo Silver camp. Spring operations already are under way in the Klondyke. The thawing of the dredges is under way and before the end of May it is expected that much hydraulic work will also be started.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Thomas J. Jones is on his way from California to London. J. R. Finlay has moved his office to 170 Broadway, New York.

J. O. Greenan is at Spokane, expecting to go shortly to China.

Wilton Shellshear is with the Miami Copper Co. at Miami, Arizona.

W. W. Taylor has returned from Korea and is now in San Francisco.

Stanley A. Easton is going to Chicago as a Wood delegate from Idaho.

George Wingfield is a delegate from Nevada to the Republican convention.

C. W. Whitley, vice-president of the A. S. & R. Co., has returned to New York.

William Dempster, mining engineer of Glasgow, Scotland, is in Utah on professional business.

E. E. Carpenter is general superintendent for the Candelaria Mines Co., at Candelaria, Nevada.

Bruce Marquard, mill-superintendent for the Sunnyside company, at Eureka, Colorado, is at Berkeley.

Morton Webber was in Salt Lake City recently, after a trip to New York. He is now at Mackay, Idaho.

A. I. Findley, editor of 'The Iron Age', New York, attended the Foreign Trade Convention in San Francisco.

Ralph S. G. Stokes is now assistant to the general manager of the De Beers Consolidated, at Kimberley, South Africa.

Frank A. Crampton and Theodore H. M. Crampton have re-opened their office at 1247 Ocean avenue, Santa Monica, California.

R. E. H. Pomeroy, superintendent of the Nevada Con. Copper Co.'s smelter at McGill, was in Salt Lake for a few days recently.

Lester E. Grant, assistant general manager for the Braden Copper Co., at Rancagua, has left Chile for Denver, Colorado, on vacation.

O. F. Brinton, general manager for the Western Utah Copper Co., has returned to his headquarters at Salt Lake City after a visit to New York.

E. H. Wolff, of the Illinois Zinc Co., at Peru, Illinois, was elected president of the American Zinc Institute, at its convention held in Chicago on May 11.

The Nevada section of the A. I. M. & M. E. will hold its annual meeting at Tonopah on June 25 and 26. John L. Dynan is chairman of the local committee.

W. V. De Camp has resigned as field engineer for the Consolidated Arizona Smelting Co. to take charge of underground mining operations for the United Verde Copper Co., at Jerome, Arizona.

D. A. Lyon, supervisor of experiment stations for the U. S. Bureau of Mines, and Thomas Varley, metallurgist at the Salt Lake City station, conferred with officials of the station at Berkeley last week.

Charles Hayden, president of the Alaska Gold Mines Co. and vice-president of the Utah Copper, Chino Copper, Ray Con. Copper, Nevada Con. Copper, and Butte & Superior companies, is at Salt Lake City. He will visit San Francisco before returning to New York.

N. Nambu, mechanical engineer for the Sumitomo Besshi Copper Co., Japan, and S. Yoshida, superintendent of the electrical engineering department, have been visiting various mining camps in the United States. They will sail from Seattle on May 27 for Yokohama.

Zinc-dust, cents per pound.....	

EASTERN METAL MARKET

(By wire from New York)

May 17—Copper is quiet and steady. Lead is inactive but firm. Zinc is sluggish but easy.

SILVER

Below are given official or ticker quotations in cents per ounce of silver 900 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine), calculated at the normal rate of exchange.

LIBERTY BONDS

According to the "Boston News Bureau," one of the main results of the cheapening policy adopted in our war financing was expressed by F. Vanderbilt as the creation of about 20,000,000 disgusted investors in the national war bonds. That disgust is the direct off-spring of the severe depreciation that their investment has suffered. Perhaps some of this cause and of this effect was inevitable; but the extent, as resulting from an unduly low borrowing rate based on an artificially low credit basis arbitrarily controlled, is larger than financial statesmanship would have permitted. At least this is clear in the retrospect, and in the consequence, concretely, the latter is a discount of over two billion—or a trifle more than 10%—on the world's premier security.

Thus, of the \$21,431,527,368 Liberty bonds and Victory notes originally issued there were outstanding on April 30, \$19,975,387,113. Continuous selling pressure has resulted in a discount in the selling price of the bonds of \$2,145,092,719, or 10.8%. There were outstanding of the first Liberty loan and converted issues on April 30 a total of \$1,952,905,730. If the proportion of converted issues of this loan has held relatively the same as for December 31, 1919, the 3½% bonds comprise about 75%, the First 4s 9%, the First 4½s 2½%, and the Second converted 4½s 1½% of the total loan. Taking the discount at which these several issues are now selling, the total for the First loan shows a reduction from the face value of the bonds of \$178,619,053.

The second loan outstanding at \$3,393,620,050 consists of the Second 4½s, which account for 83% of the total, the remainder being the Second 4s. At the current discount the depreciation from the issue price is \$473,843,843. The Third and Fourth loans contain but one issue each, the Third 4½s and the Fourth 4½s respectively. The depreciation for the Third loan is \$405,860,247 and for the Fourth loan \$391,519,930. Of the \$4,404,861,650 Victory notes 79% are 4½s, and 21% are 3½s. The respective discounts are \$138,814,239 and \$70,788,837.

Somewhere around 20,000,000 different individuals and companies were subscribers to war loans. These bond purchasers have sustained, at present market prices, a loss averaging \$108 per subscriber—the result of selling the bonds on an artificial money market sustained by the Federal Reserve Board at a level far above the actual conditions warranted. Allocating the loss to our entire population it is found to be \$19 per capita.

It is true that as citizens, the investors in war bonds share in an indirect double profit that Uncle Sam makes—in his paying less aggregate annual interest than he otherwise would in his redemption of a considerable part of these obligations well below par. The Treasury, through the sinking fund, has bought back, at an increasing discount, \$1,456,000,000 of war bonds to date, bringing the outstanding total to just under 20 billions. This means a saving along in annual interest of almost \$58,500,000, or more than a million a week.

But that is cold comfort for the individual bondholder, confronted with his own specific loss in principal, and either handicapped in ability or puzzled in judgment—in view of a lost and increasing debt of redemption, and the chance it will be increased perhaps 50% further by bonus legislation—as to whether the time has come to try to 'average' such losses.

MONEY AND EXCHANGE

Foreign quotations on May 18 are as follows:

Foreign, dollars:	Cable.....	3.84½
Sterling, dollars:	Demand.....	3.83½
France, cents:	Cable.....	7.04
	Demand.....	7.02
Lire, cents:	Demand.....	4.97
Marks, cents:	Demand.....	2.17

Eastern Metal Market

New York, May 12.

All the markets except that of tin are inactive. They are all more or less depressed as an after effect of the railroad strikes.

Demand for copper from domestic consumers is light. Prices are a 'shade' easier.

Buying of future tin by dealers has been heavy. Prices are much lower.

There has been a decided reduction in lead prices and buying is only fair.

The zinc market continues lifeless with quotations nominally a little lower.

Antimony is dull and lower.

IRON AND STEEL

Seldom, if ever, have iron and steel consumers suffered so generally from a lack of material as at the present time, says "The Iron Age". That steel-plant and foundry operations are heavily curtailed or shut off altogether without loud cries of complaint, is explained by a realization that mills are not to blame for the railroad strike and that if manufactures cannot be shipped it is not surprising that raw materials are not received.

It is estimated that 1,000,000 tons of finished steel is standing, loaded on cars and stored in works and mill-yards. In Chicago the Steel Corporation has now 21 furnaces active out of 29 and its operations are at a rate of fully 80% of ingot-capacity. The leading independent there has maintained operation at 70%. Fuel scarcity has been a major factor. One Eastern plate-mill has lately been unable to get more than 50% of its normal production. A sale of 1000 tons of foundry iron to Germany, the first for years, has been made.

The statistics of ingot production for April indicate a total for the country of 3,139,710 tons, or 120,760 tons per day, which is a reduction of about one-sixth from the March output of 145,000 tons daily. In the four months of this year the country has apparently produced 14,000,000 tons.

COPPER

Prices of leading producers have undergone a slight revision but the market is statistically strong. Electrolytic or Lake copper is quoted by leading interests as 19 to 19.25c., New York, for early delivery, but demand is light. There still exists an outside market where prices range around 18.75c., New York. It is a fact that stocks have been decidedly lessened lately because of labor troubles and that production has been considerably curtailed for the same reason. The trade position of the market is, however, excellent, so far as the future is concerned, if present conditions become better and no labor troubles develop. Buying for foreign account continues relatively of fair proportions. As a result of the financial arrangements to facilitate purchases by France it is estimated that that country will take about 8000 net tons per month.

TIN

A fairly heavy business has been done the past week, largely with dealers as buyers. It has been for future-shipment metal, principally, and amounted to over 1100 tons. The transactions took place mostly on the New York Metal Exchange. On Wednesday, May 5, it is estimated that 300 tons was bought; on the next day 100, and on the next 425 tons. On Monday this week, at least 225 tons was involved. The report that as high as 2000 tons changed hands on Thursday, May 6, is not credited. The price range was from 58c. on May 5 to 55c. on May 10. This movement was brought about by a decided speculative decline in the Lon-

don market last week. Consumers of tin have not been interested, however, and there is no doubt but that tin consumption has been exceedingly curtailed, some mills being closed down. While most consumers are pessimistic, they have begun to show more interest. Spot Straits tin, New York, has ranged in the last week from 58c. on May 5 to 55.50c., New York, on May 10. Yesterday it was 56.25c., New York, while in London it was £312 per ton. Arrivals thus far this month have been 2260 tons with the quantity afloat reported at 4270 tons.

LEAD

There continues to be a moderate inquiry for prompt lead. However, those who possess it are either holding it or parting with it only in small lots. The values range around 8.75 to 9c., New York, were there any to sell for this delivery. The American Smelting & Refining Co. late on Friday reduced its price ½c. per lb. to 9.25c., St. Louis, or 8.50c., New York. Various reasons are given for this step. One is that the London market broke late last week so as to permit of imports of lead to a figure that would include the duty and cut the leading interest's price of 9.75c., New York. The outside market was already at 8.75c., New York. Some business was transacted as a result. Another reason advanced is that since the metal can now be moved on contract with great difficulty, the price has lowered so as to buy ores advantageously. The two reasons are given for what they are worth. The quotation today for early delivery is 8.25c., St. Louis, or 8.50c., New York, with demand light.

ANTIMONY

The market is quiet and lower at 10c., New York, duty paid, for the higher grade with the lower grades around 9.50 to 9.75c., New York, both in wholesale lots, for early delivery.

ALUMINUM

Quotations for wholesale lots of virgin metal for early delivery are unchanged at 33c., New York, from the leading producer and at 31.50c. from other sellers.

ORES

Tungsten: Business is flat and quotations are nominal at \$7 per unit for Chinese ore. Higher grades are valued up to \$15 per unit.

Ferro-tungsten is quoted at 85c. to \$1.15 per lb. of contained tungsten.

Molybdenum: Quotations are nominal and unchanged at 75c. per lb. of MoS₂ in regular concentrate. There is no demand.

Manganese: High-grade foreign ore has sold at 83c. per unit, seaboard, the highest price in many months. There is a distinct scarcity, the imports for the first quarter having averaged only 14,846 tons per month or the lowest in seven years.

Manganese-Iron Alloys: Because of the failure of some producers to deliver ferro-manganese on contracts as due, some consumers are reported to be seeking other supplies and therefore the demand for early delivery is a little brisker. For this position \$250 is asked and easily obtained when the alloy is available. For last half quotations are unchanged at \$200, delivered, for domestic alloy, and \$195, seaboard, for a limited quantity of British alloy for shipment during August and later. The situation in Great Britain is such that calcium silicide is being used as a substitute for ferro-manganese as well as certain silico-manganese alloys. The Anaconda Copper Co. is understood to have in operation a fourth electric furnace making ferro-manganese.

T. A. RICKARD, . . . Editor

SAN FRANCISCO has been the place of meeting for many conventions lately; a few days ago the World Metric Standardization Conference was in session here. A large number of addresses were read in advocacy of the adoption of the metric system. It seems obvious that the change should be made and that the longer it is postponed the costlier it will be; but the item of chief interest concerning this convention is the fact that Mrs. E. L. Stephens of Bakerfield received a prize of \$1000 for the coining of a word to express the idea of "The United States and Britannia in unison in world measurements and weights". Our informant spelled it "Brittania", probably in order to justify Mrs. Stephens, who was the first to suggest "Unitania". The lady of Bakersfield found an easy way of making a little honest money.

VENUSTIANO CARRANZA was no friend of the United States or of American miners, but his ending by a hideous assassination is bad news. We are glad that General Obregon deplores the act and condemns those who ought to have defended their chief. The most pitiable feature of the crime is the fact that nobody seems to know for certain on which side, Federal or revolutionary, the assassin, Colonel Rodolfo Herrero, stood. Apparently the First Chief, as he called himself, was the victim of one of those acts of cowardly murder that have been so numerous since Diaz was ousted from office ten years ago. We hope that Obregon and his friends will be able to prove their detachment from the crime of Tlaxcaltenango, so that the new regime may not be stained at its start as was Huerta's, for complicity in Carranza's death would compel the United States to refuse recognition of the *de facto* government now apparently securely established in Mexico. The outlook for a general resumption of mining in Mexico is good.

IN his valedictory letter, on resigning as Director of the U. S. Bureau of Mines, Mr. Manning took the opportunity to express his regret that those in the Government service, more particularly in the scientific departments of its administration, are paid so inadequately that they are compelled to accept the tempting offers made to them to enter the service of corporations. Although "the Government spends each year many millions of dollars in useful scientific work for the benefit of the whole people", it does not recognize the service of its scientific and technical servants so as to enable them to remain in

its service. The money wasted in Government publications of a useless character, particularly in the printing of piffle in the 'Congressional Record', and in documents designed to minister to the glory of inconsequent individuals, would go far to correct the insufficient salaries of the staffs in the Bureau of Mines and the Geological Survey.

CONCERTED determination on the part of the mining companies at Butte to rid the mines of members of the Industrial Workers of the World, even if some of the properties are compelled to suspend operations for a time, is the result of the recent strike, which was declared off by the I. W. W. members on May 13. The resolution that ended the strike provided that the fight be again transferred to the 'job', which means that the men return to work, but resume with renewed energy the system of sabotage that the self-appointed leaders promise will finally weaken the industry to such an extent that the 'fellow-workers' can seize and operate the mines for their own benefit. On April 2 a mob of strikers collected on Anaconda road for the avowed purpose of preventing anyone, even mechanics, engineers, and shift-bosses, from going to work. The sheriff of Silver Bow county, with a small force of deputies, endeavored to persuade the crowd to disperse. Several fights started and presently a shot was fired, whether by one of the mob or by a deputy sheriff was not established. This started a fusillade, lasting several minutes, in which eight or nine of the crowd were wounded. Later Thomas Manning, one of the strikers, died in a hospital of a gunshot wound presumably received in the riot. The immediate effect was to stop the picketing, which had been unusually aggressive, and the vicious defiance of the strikers, which had intimidated practically all the men who wanted to go to work, disappeared abruptly. Evidence introduced at the inquest on the death of Manning revealed the real principles and plans of the I. W. W. organization. A special agent of the Department of Justice, who in the discharge of his duty attended meetings of the strikers, testified as to the threats of violence made at these sessions, and introduced as evidence copies of 'Solidarity', 'The Revolutionary I. W. W.', 'Sabotage, Its History, Philosophy and Functions', and other radical literature that he had obtained at union headquarters. More than a dozen members of the mob, who were presumed to refute the testimony of the sheriff and his deputies,

admitted that the average of their daily earnings had been more than \$7.50, while \$9.72, \$9.37, and \$8.96 were among the individual averages. Still, they were alleged to be striking for \$7 per day. This is explained by the evidence of three I. W. W. organizers, who frankly declared that even \$15 per day would not be acceptable to the men. The strike, both off the job and on, is simply a weapon in a class war; the object is to cripple the industry with the ultimate purpose of taking possession of the mines by a soviet. As we have said before, a large majority of the miners at Butte are ready and anxious to work under present conditions and at the prevailing wage; moreover, that these conditions and wages are acceptable is, in effect, admitted by the agitators themselves. It is obviously to the advantage of both employers and the law-abiding miners that the individual members of the I. W. W. be shut out of the mines. While it will be impossible to identify all of them, and while some injustice may be done in barring men who are not members, the companies are right in refusing to employ any man to whom suspicion points as being an exponent, even if only as an unfortunate dupe, of the vicious principles for which the I. W. W. stand—namely, sabotage, violence, anarchy, and government by a soviet minority.

ON another page we publish a description of the new mill at the Modderfontein mine, which is the greatest gold mine in the world today. The notable features of this mill are (1) the use of Nissen stamps, (2) the gravity flow of all the pulp from the stamps to amalgamated plates so that only one elevation of pulp is required, (3) the continuous treatment of the slime in Dorr thickeners and Brown agitators (or pachucas), and (4) the complete separation of slime from sand by classification, followed by the collecting of the sand and its treatment in the same vat, as at the Homestake. We understand that Mr. Francis L. Bosqui, formerly of California, was consulting metallurgist to the company at the time the scheme of treatment was devised. The Nissen stamp has averaged a duty of 30 tons per day through 9-mesh screens for the last four years. To do this it has consumed 4.06 horse-power. It has reduced the cost of crushing on the Rand 24 cents per ton for power alone. While we have had reason formerly to criticize the self-complacency of South African millmen, it must be confessed that they have not disregarded the lesson of the experiment with the Giescke ball-mill in 1911. They have been willing to accept suggestions from the outside in regard to the bettering of their stamp-milling practice and even to give a fair trial to the Nissen single-stamp battery after it had gone out of favor in this country. The Nissen stamp is being used successfully at the Faleon and Shamva mines in Rhodesia. It is strange, to say the least, that it was not considered in the design of the Gastineau and Juneau mills, in Alaska, particularly of the latter. Instead, ball-mills borrowed from cement practice were bought in a hurry and a plant was erected that has been undergoing remodeling ever since. The Nissen stamp is the inven-

tion of that excellent engineer and gallant soldier, Mr. P. N. Nissen; it was used in the Boston Consolidated mill, at Garfield, 15 years ago, but never seemed to become popular in the United States. The remarkable success of this crushing machine at the Modderfontein should arouse the intelligent curiosity of our Western millmen.

The Strategy of Minerals

On May 17 a special report, prepared by Mr. Frank L. Polk, Assistant Secretary in the Department of State, was presented to the Senate, by order of the President, on the subject of restrictions upon American participation in the oil industry of foreign countries. The information was confined largely to conditions existing under the British flag. The report outlined British policy as follows: (1) To deter foreign nationals from owning or operating oil-wells in the British dominions; (2) the Government to participate directly in financing the larger oil-ventures; and (3) to prevent British companies from selling their property or transferring their shares in British-owned companies to foreigners.

Of course, these restrictions are not aimed at Americans particularly, but are directed against aliens generally. In Mexico, the report says, it has been found necessary to send a warning against any procedure resulting in confiscation of American oil-holdings. The Mexican threat to confiscate, however, has aroused much less interest than the disclosure of British policy, which, says the report, "would seem to be justified from the viewpoint of international law, however impolitic it might be as regards reciprocity and international comity". We think the policy is mistaken as a matter of national economics and we consider it regrettable for its effect upon international good-will. Before proceeding to discuss further the question of American enterprise on British oilfields, let us turn to the Leasing Act recently promulgated for the exploitation of our own oil resources. This Act restricts the leasing of land containing oil, coal, and phosphate to citizens of the United States and to corporations organized under the laws of the United States; further, "citizens of another country, the laws, customs, or regulations of which, deny similar or like privileges to citizens or corporations of this country, shall not by stock ownership, stock holdings, or stock control, own any interest in any lease acquired under the provisions of this Act". This seems eminently fair, and, as yet, no report has been made to the British parliament suggesting that it is not. Under our mining regulations, no alien can locate a claim; in Canada, an American has an equal right with a Canadian to locate mining claims, this privilege being denied only to enemy aliens, that is, the Germans and their late partners in the War.

What is the purpose of these international restrictions? To preserve a national resource for the national benefit, we presume. Do the restrictions fulfill this purpose? We think not. If an oil-well in Burma is productive, it should make no difference to the British government, it seems to us, as to who owns or operates it, provided the product goes to the British market, for use, let us say, by

the British navy. If the well is owned by an American company, the product will still go to the British market, which, we believe, offers the best price to anyone operating in Burma. On the other hand, if a British company controls oil-land in California, its product is sold in this State, and the producer has nothing to say in regard to its ultimate destination; the distribution of the oil is in American hands. It would be right and proper, from an economic standpoint, if the governments of the United States and Great Britain were to insist that the oil produced in their territory must be rendered available for the use of their own people by sale in their own market; but the embargo upon the participation of foreigners in the exploitation of the mineral is illogical. Take the case of the oil-well in Burma. It should not matter to the British government whether the winning of the oil be in British or foreign hands, provided the oil resources of Burma were not being exhausted for the benefit of a foreign nation. If American capital be at the back of the enterprise, it should not be begrudged a reasonable return. After all, in the aggregate there is more money put into metal mines and oil-wells than is taken out of them; we hear much about the lucky ones; we forget the unlucky. Much more British capital, for example, has been put into mining enterprises in this country than has been taken out as profit; of that there is no question. It is not often that the entire capital of a mining enterprise (which includes oil) is recovered in profit, plus interest on the outlay. Many Americans in the British dominions and many Britons in the United States have spent their substance in unavailing search for sudden wealth. The few prosper greatly, the many have the meagre satisfaction of helping to develop the waste, or the lonesome, places on the map. If our known oil resources are insufficient, if we are threatened with a scarcity of this valuable mineral, then it were provident to prevent the exportation of it to foreign countries, that is, the consumption of it by any but our own people; but it does not matter who is engaged in the actual winning of it from the ground, unless, of course, the foreigner's participation in the enterprise excludes domestic capital from a profitable opportunity. This rarely happens. As a matter of fact, the purchase of mineral lands by foreigners, whether in Burma or California, helps the residents by augmenting the price of local property and by bringing capital into the district, where this capital becomes so securely anchored that most of it remains, for the benefit of the district and the State. To come to bedrock, it does not matter who exhausts a national resource, such as oil, wastefully, whether it be a citizen or an alien. It is squandered, from a narrowly national standpoint, if more is produced than is consumed domestically. That is true if oil, for example, is more valuable to our people than the things that we obtain in exchange for the oil we sell abroad. The whole world is suffering from shell-shock; the peoples and their governments show a meanness of spirit in pitiful contrast with the fine emotions evoked by the War. It would be more logical, if, instead of imposing restrictions, or kicking at

those imposed by others, we were to go forth into foreign lands ourselves and engage in mining there, leaving our own mineral resources intact for the benefit of our American posterity. That sounds whimsical, but it is more reasonable than the policies adopted by the two English-speaking governments. The fact remains that the United States is the creditor nation of the world today; its manifest destiny therefore is to engage in foreign exploitation; the logic of events will render it advantageous for all concerned to facilitate American mining enterprise outside the United States. It should be our policy, therefore, to remove restrictions upon foreign undertakings in our country, because, to be frank, such enterprise, owing to the financial conditions prevailing in Europe, is likely to be much smaller in scope than our own enterprise in foreign parts. It should be the policy of our Government to encourage our nationals to exploit the mineral resources of foreign lands and to give its utmost protection to its citizens in doing such useful work.

A Distinction and a Moral

Employees of industrial companies may be divided into two fairly distinct classes: (1) those who have an appointment and draw a salary; (2) those who have a job and receive wages. Speaking generally, the members of the first group wear white collars, whereas the wage-earners, by and large, are content with an article of apparel commonly known as a 'work-shirt', the distinguishing characteristic of which is a permanently attached collar of the same material as the shirt itself. It has always been true that of two equally competent and experienced men the one who wore the white collar was paid less money, for the reason that the ratio of supply to demand was generally greater in his kind of work. For instance, when the plumber and the miner got \$4 per day, the bank clerk and the assayer were paid \$90 per month. This difference, to a large extent, is justified by the greater likelihood of advancement for the salaried man; his position is a stepping-stone to the place of the well-paid executive. A committee of Engineering Council, in a recent report, calls attention to a subtle difference between the 'cost of living' and the 'value of the dollar'. The committee believes that many classes of salaried engineers and technical men refrain from pressing claims for increased compensation on the ground that they are unable to live in the style to which they have been accustomed, simply because they feel it undignified to ventilate a matter that is in the nature of a private affair; they believe that it would not be worthy of their white-collared status. If, however, the question is put in the light of a change in the value of the dollar, the position is taken that the engineer may properly maintain that he is entitled to a sufficient increase in pay to make his remuneration equivalent in purchasing power to what it was five years ago. This is a nice distinction, yet it is worth thinking about. The fact remains that the changes due to the War have created a much greater disparity between the earnings of the man

who works by the day and of the man who works by the month. The wage-earners have demanded and received increases out of proportion to those of the salaried men. As an illustration, sub-foremen in the shipyards are paid at the rate of \$2900 per year, whereas marine designing-engineers in responsible positions are paid but \$2400, which is approximately equivalent to the income of an ordinary journeyman in many of the metal trades connected with the shipyards. Assayers, chemists, draughtsmen, surveyors, and junior engineers employed at mines and metallurgical plants are generally salaried men, and, while a somewhat similar situation obtains in the mining industry as is found in the shipyards, many companies have provided for employees of this kind, to some extent at least, by means either of bonuses or of outright increases in salary. Some companies doubtless have taken advantage of the over-supply of technically trained men, coupled with their characteristic backwardness in asking for more, to avoid giving deserved increases of pay. Such a policy, if continued, can have but one ultimate result, namely, a definite deterioration in the type of men who will select such work for a career. While all young engineers hope to become high-salaried mine-managers and consultants, not many achieve their ambition; therefore there must be a prospect of reasonable remuneration somewhere below the top. The Federal, State, and municipal governments have always been notorious for the low salaries they pay technical men, and the disparity between Government and private salaries has been emphasized during recent years. One immediate result has been as many as seven resignations from the U. S. Geological Survey in one week, while the Canadian Survey has been decimated. A belated effort is being made to correct this manifest inequality. An amendment to the Rivers and Harbors Bill has been proposed in the Senate providing for an increase of 25% in the prevailing salaries of assistant and junior engineers and chief clerks employed on all work related to the improvement of rivers and harbors and the construction of fortifications. This has been done at the solicitation of the American Association of Engineers. The St. Louis chapter of this organization was recently instrumental in causing an advanced schedule of salaries to be adopted by the board of aldermen, for determining the remuneration payable to all engineering and technical employees of the municipality. It appears that when the essential facts, including a comparison with the prevailing rates elsewhere, were presented in a comprehensive and logical way, the board was convinced that the employees were entitled to the increase for which they asked. There is one phase of this subject that is rarely appreciated, although it concerns directly the financial success of the employer. The cost of the engineering supervision of any enterprise, whether it involve construction, maintenance, or operation, represents only a small part of the total expenditure. The proportion, of course, varies between wide limits, but 5% may be taken as an approximate average. If, then, as a result of increased competence on the part of the

engineering and technical staff the efficiency of operations as a whole be increased by only 1%, the saving would be sufficient to provide an addition of 20% in the compensation of the engineers; and, as the engineering is a vital factor in the economies of an undertaking, the wisdom of obtaining the best available men, even in the minor positions, becomes apparent. For instance, a second-rate transit-man at \$150, in the course of a month may be responsible for waste in the time of common laborers amounting to thousands of dollars. Nor need he necessarily make gross or obvious blunders, for which he may be discharged; the loss may simply result from lack of foresight, from ineptitude, or, perhaps, from minor errors, all of which a higher-grade man at \$250 per month would avoid as a matter of course. And yet some employers 'economize' on engineers because they can; whereas the wage-scale of the laborer is fixed by agreement with unions or by the prevailing rate in a particular locality and does not offer opportunity for cheeseparing. There are, of course, certain positions, which are commonly held by young men, generally recent graduates from the technical schools, that are in the nature of apprenticeships. As a rule these boys have no family responsibilities and at any rate they expect to remain in such positions only temporarily on the way to posts of greater importance. It is reasonable—in fact, it is fortunate—that such positions should pay small salaries. It is in the intermediate grade of position, in which we find the average man who does his semi-routine work well, but has not the qualifications of initiative or personality to fill the place of the more fortunate specialist or executive, that the difficulty arises most frequently. These are the men on whose loyalty the employer feels he can count; they are educated and informed; they compose a large part of the substantial middle class in every community; they come under the category of 'white collar' men; and commonly it is these who have been accorded less consideration than any other class in the adjustment of salaries to keep step with increased prices. It may be argued that considerations other than salary make such work more desirable, so that it is unnecessary to pay more. The theory may be advanced that the law of supply and demand regulates what must be paid and that the same man would not be more efficient if his salary were increased by 25%. This brings us back to the crux of the whole question, namely, the necessity for adequate compensation to prevent inevitable deterioration in the type of man who will train himself for an important and necessary kind of work. The process of devolution may be slow, but it will become sure unless a sufficiently attractive future is to be expected by those whom it affects. Applying this reasoning to mining engineering, in which we are more directly concerned, can the manager afford to take the risk? The efficient conduct of his business depends largely, and directly, on the competence of his technical staff. In the interests of his stockholders he must maintain the standard of that part of his organization which is symbolized by the wearing of the white collar.

DISCUSSION

Our Anniversary

The Editor:

Sir—So the 'Mining and Scientific Press' is sixty years of age, and is going to issue a diamond jubilee number on its birthday!

No one would believe it is so old by its appearance, for, surely, it is brighter and prettier and more energetic and cheerful than ever it was before. My memory of it goes back 30 years, during which I have been, more or less—chiefly more—one of its regular readers and admirers, and it seems to me to be growing younger. May I quote something I read recently which may explain the phenomenon? It must be that "at 60 it has the love of youth so clearly in its breast, that it can never cross the line to age". And it never will grow old so long as it possesses the high ideals of conduct, sincerity, and truth that guide its production, and for which it is read and honored.

The paper is unique among technical journals in that the professional aspect is not its only one; that there is another side to the mining engineer than the business side is not forgotten, and it is the remembrance of that which attracts us to its pages. As no profession involves a wider acquaintance with the application of the sciences and the arts to the exploitation of Nature's wealth, and as none leads a man through more varied scenes of beauty and grandeur, and of desolation and barrenness, so none, not excepting the physician's, brings one into contact with so many varieties of mankind, as does that of the mining engineer in our time. So we should have the human side of life presented to us, and it is fine that our weekly mining journal should remind us that men have minds and souls, as well as brains and muscles, and that the development of brain and muscle is not the only object to which the mining engineer should devote his life.

As an Australian reader, it is a pleasure to send greetings and the best good wishes to the 'Mining and Scientific Press' on its attaining 60 years of age, and to testify to the excellence of its writing, its printing, and its illustrations: the last are noteworthy among journals, not photographs only, but veritable works of art are they. The Editor we always knew as an artist in words; of late years he has shown us that he has also the artist's eye for scenery.

What else is there to add? Mining engineer, geologist, journalist, poet, preacher, artist, gentleman—the 'M. & S. P.' aims at making the first comprise all the rest.

May it succeed, and remain ever in the forefront of youth, and so "never cross the line to age".

With sincere congratulations and warm personal thanks for the knowledge gained and the pleasures enjoyed over many years' perusal of its pages by one, at least, of its trans-Pacific readers.

EDGAR HALL.

Silverspur, Queensland, March 30.

Complex Ores in California

The Editor:

Sir—I have read your article on the treatment of complex ores in California, wherein you make special reference to metallurgical operations at the Afterthought copper mine. As your article creates somewhat of a false impression regarding the operations of that company, I will endeavor to answer it and clear up a few points in question.

First you speak of the failure of all metallurgical processes so far tried on Afterthought ores. These processes were no more failures than any proved simple process is a failure that must be discontinued owing to a rise in the cost of treatment or in freight-rates, or a drop in the market-value of the metals produced.

There is nothing really difficult in the treatment of complex ores in California, and a number of processes are available for almost every one that we have in this State. The kind of process to be used is dependent on the situation of the property, the character of the ore, and the quantity of ore in reserve. As a rule the most economical process from which the greatest recovery might be expected is the one with which is connected the most extensive plant or initial cost, but the amount of money that can be safely expended on a plant is dependent upon the quantity and grade of ore developed.

As regards the Afterthought ore, which is similar to the Bully Hill and other Shasta county ores, it is one that cannot be concentrated successfully by gravity methods owing to the extreme fineness of the sulphides and the presence of barite and a large amount of pyrite. At the Afterthought successful results were obtained with hot-blast smelting, between 1905 and 1907, on the upper-level ore which was more or less sorted so as to obtain a minimum amount of zinc with a maximum amount of copper. As the zinc content of the ore-reserve increased, this method of smelting became out of the question.

S. E. Brotherton, who was in charge of the property at the time, made experiments with ammonia leaching. He obtained good results and made progress on a small

sidered. At that time, however, there was no mill so that the residue from his leaching would be low in copper. Moreover, since there was no reverberatory furnace, nodulizing, briquetting, or sintering would be necessary before the ore could be smelted in the blast-furnace. If the ammonia process had been used at this time in conjunction with a mill and reverberatory, there is no doubt in my mind that the process would have been a success, since concentration would have given a residue carrying more than twice the amount of copper that could be obtained from crude-ore treatment, and the residue could then have been fed direct to the reverberatory. Then again, the waste heat obtained from the reverberatory could have been utilized for distillation purposes, as the steam required for distillation is one of the largest items in the cost of the ammonia process, as is shown by work now being done with this process on copper ores.

The Afterthought mine remained idle until 1917, when J. F. Milliken, of St. Louis, undertook to operate it under the direction of John Tait Milliken, his consulting engineer. Extensive tests were carried on with a view to finding the most economical process for this ore, and I understand that two stood out above all the rest, namely, the Horwood process and the electrolytic method. Tests carried on by competent engineering companies, with a view to employing some wet selective method, such as the Bradford process, proved failures. The electrolytic method as applied to zinc ores was in the first stages of its commercial development, and reports from companies trying this process at the time were far from encouraging. It seemed far too expensive for any pioneering work. We know now that the Anaconda Copper Co. alone has spent millions in the development of this process and the building of a plant. From the start the Horwood process gave exceptional results on a small scale, and although it was realized that a certain amount of pioneer work would be necessary, it was the only process that seemed available at the time. After about six months of running the Horwood process was developed to a point where it could be called a real commercial one for ores such as the Afterthought, for, contrary to an idea prevalent among the mining public, the process is no more difficult of operation than the average complex-ore method.

During this time the electrolytic process was making headway at other plants, and, knowing that if it were once developed it would offer greater possibilities than any concentration method, all the equipment was so chosen and erected that it could be utilized at some future date for electrolytic work in case the management found it desirable to make the change. Another point that should be mentioned in this connection is that at this time the ore-reserve did not warrant the great expenditure which would have been necessary in the installation of the electrolytic process, whereas it was thought that profitable operations could be carried on with the Horwood process while further developing the mine.

Before making final changes, which were necessary in order to put the plant on a profitable basis, J. F. Milliken

died. Operations were at a standstill for about eight months, although during this time a smelter, which had been started before Mr. Milliken's death, was completed, the intention being to handle the residue or copper concentrate from the preferential process. By the time the smelter was completed a number of factors had intervened, which not only made the Horwood, but all other concentration processes out of the question. Up to the year 1919 it was possible to realize, on a concentrate containing 45% zinc, 8 oz. silver, and 3% copper, approximately \$25 per ton after deducting smelting and freight charges to Oklahoma. This was on a market-value of zinc at 7½¢ per lb., silver at 50¢. per oz., and copper at 15¢. per lb. But throughout the greater part of 1919 and especially during the past few months with the same grade of concentrate and a market-value of the metals much higher than the above quotations, the product was practically worthless. This was due to a rise in the cost of smelting zinc concentrate, and an absolute refusal by all zinc-smelters approached to pay for any silver or copper contained in the ore. These are the main reasons for the suspension of operations by a concentration process at the Afterthought mine. Had Mr. Milliken lived, he undoubtedly would have financed the construction of an electrolytic plant in the spring of 1919. Had conditions remained more normal as regards the disposal of the zinc concentrate, any small difficulties of operation at the present plant could have been worked out, and not only could the mine have been developed, from the profits of the operation, but an electrolytic plant and all other needed construction would have been possible.

When it became evident that it was not profitable to market the zinc concentrate, all efforts at preferential flotation were discontinued, and in order to assist development in the mine and to determine the practicability of smelting a charge similar to that derived from an electrolytic plant, it was decided to make a collective concentrate and smelt it direct in the reverberatory furnace, shipping only copper matte. In all cases where a residue from an electrolytic plant has been smelted, it has been mixed with other ores so as to bring down the proportion of zinc in the charge. Some doubts were expressed by metallurgists experienced in electrolytic work as to whether or not a zinc-plant residue, which might at times contain as high as 16% zinc, could be smelted directly in a reverberatory furnace. The Afterthought management felt sure that if a collective concentrate, containing a high percentage of sulphur, as compared with the sulphur present in an electrolytic residue, could be smelted, there would be no doubt of their being able to treat this material. In the first few months of operation some little trouble was experienced, while running on charges containing not more than 12% zinc, but this was traced to sources other than the presence of zinc, and during the last few months operations were absolutely smooth although the zinc content of the charge seldom dropped below 17% and for weeks at a time it averaged well above 20%.

The above process at its best was wasteful, as the zinc

content of the crude ore in the mine averages above 16% and has a higher gross value than all the other metals combined. For this reason, after determining that it was an easy matter to smelt an electrolytic residue, it was deemed advisable to suspend operations until an electrolytic plant could be built, notwithstanding the fact that during the last couple of months of operations a profit was realized on the sale of copper matte alone.

Such is a summary of the history of metallurgical operations at the Afterthought mine. Experimental and investigation work was constantly going on, not only on processes that were being used commercially at other plants, but on practically every new process that came to our attention and that seemed to have any merit. Among these processes were electrolytic zinc, concentration smelting, ammonia leaching, magnetic separation, Bradford, Terry, and other selective methods, volatilization, and various leaching and digestion methods with chemical precipitation. Samples were sent out constantly upon requests of individuals or corporations that claimed they had a process which would more successfully treat the Afterthought ore than any other that we had investigated. To my knowledge, not one of these individuals or corporations was heard from again. Wet preferential flotation by the use of reagents was given a thorough test on a large scale in order to compare it with the Horwood process, but it proved inferior for this particular type of ore.

The decision that the electrolytic process was the best known commercial process for Afterthought ore was based on the following:

1. The character of the ore is nearly ideal for this particular process. There is a complete absence of such metals as cadmium, nickel, bismuth, cobalt, vanadium, arsenic, and antimony. Analysis of concentrated fume from the smelter failed to show even a trace of these metals. In an experimental test-run at Anaconda on Afterthought ore a zinc cathode 99.9% pure was obtained without any purification.

2. The cost of power, one of the main items in electrolytic work, is very reasonable at the Afterthought plant.

3. The electrolytic process has been so fully developed that no pioneering work would be needed on an ore containing so few impurities.

4. All equipment at the Afterthought plant can be utilized to advantage in connection with an electrolytic plant.

5. If a demand for zinc oxide or the salts of zinc should arise, they could easily be obtained by by-passing part of the leach-solution.

California is in need of either a custom zinc-plant situated near some cheap fuel-supply, such as the San Joaquin oil-field, or a custom electrolytic plant where cheap power is available. This would not only stimulate renewed activity at all the larger properties, but the smaller ones throughout the State would be in a position to concentrate their ores, for the Californian mines that warrant other than concentrating plants are few in number. With an outlet to a near-by zinc-smelter, preferential methods would no doubt be necessary in most cases

in order to obtain a concentrate high enough in zinc; but with an outlet to an electrolytic plant, the cheaper collective method of flotation would afford all the preliminary treatment necessary, as a far lower grade of ore can be treated profitably in an electrolytic plant than is possible at a smelter. The only drawback to a custom electrolytic plant is the variety of impurities, which would change constantly with different lots of ore, and would add to the cost of treatment.

There are other processes by which products such as zinc oxide or sulphate might be obtained, instead of a concentrate or spelter; many of them are promising, but very few have been demonstrated successfully on a working basis. It is my opinion that if one were producing upward of 30 tons of zinc oxide daily, a market would be hard to find, although of late, through the activities of the New Jersey Zinc Co., a considerable market for this material is being created. In Colorado there was an example of concentration smelting carried on successfully, but only part of the zinc oxide produced was marketed, the rest was treated in Iowa by electrolytic methods. With an electrolytic plant one could easily switch part of the zinc-sulphate solution, to be treated separately by certain chemicals, such as the basic or alkali carbonates, to form zinc carbonate, which could then be calcined to zinc oxide. Or if there is a demand for zinc sulphate, which commands a comparatively high price, it is a simple matter to obtain this salt by the use of evaporators such as are used in industrial chemical work. But if there be a big demand at present for the oxide and sulphate of zinc, why does not a progressive concern such as the Anaconda company utilize such simple methods to obtain these products from part of the leach-plant solution? We know from their work in making finished products that the management would take advantage of all such possible operations, if such products yielded more profit than the zinc deposited electrolytically.

You state in your editorial that in all accounts of operations at the Afterthought mine you have not seen to what extent zinc can be removed from the collective concentrate by giving it a sulphatizing roast, followed by leaching with acidified water derived from passing roaster-fume through suitable towers. You evidently have reference to the article printed a short time ago on a modification of the Horwood process in which this suggestion was made. As yet it has not been possible to obtain a complete sulphatizing roast with complex ores on a large scale. In electrolytic plants they work to obtain as much of the zinc in the sulphate form as is possible, but the proportion of zinc sulphate to zinc oxide so far has been very small. To leach out any appreciable amount of zinc oxide, the acidity of the leaching solution, I believe, would have to be much stronger than that obtained by merely passing the roaster-gases through simple absorption-towers. If one were to go so far as to erect an expensive plant to obtain sulphuric acid from the gases, one would not be as well off as if one had an electrolytic plant, in which very little, if any, sulphuric acid is added once the circuit is filled and the plant in operation, but by leaching and precipitating by

chemical means, fresh acid must always be added for the leaching.

As regards the above-mentioned article, in which the use of a slightly acidified solution is suggested for the Horwood method, one comes back to concentration processes. I have tried removing the small amounts of sulphates formed in roasting, but found that the copper sulphate in the pulp was absolutely necessary for subsequent flotation of the zinc sulphide. The pulp was very acid in reaction, but there was no apparent cleaning of any zinc oxide formed on the zinc-sulphide particles. Then, again, a point had been reached in Horwood practice when it was a simple matter to control the roast, so that no great amount of zinc sulphide was altered in roasting. Before the process was improved in this regard, the use of acid from the smallest to prohibitive amounts was tried, but no improvement was noticeable. At the same time there is no doubt that the suggestions offered might lead to some interesting refinements in the Horwood process.

This discussion refers mainly to the zinc-copper ores of the northern part of the State, but methods mentioned as being applicable to these ores should not differ radically from the treatment for the lead-zinc ores found in the southern counties. Although I have stated that for ores such as the Afterthought, the Horwood is the best concentration method, for lead-zinc complex ores I have found the Bradford to be the best preferential flotation method.

A. H. HELLER.

Ingot, California, May 12.

The Editor:

Sir—Referring to the editorial on this subject appearing in your issue of April 24, the failure to exploit many of the mines that produce ore of this character may be ascribed to causes in themselves complex. These ores may be difficult to treat; but the aggregate value of their component metals is high, and with hydro-electric power available along the Sierra and the markets of the world accessible by sea, the effort in seeking to make commercial use of this storehouse of potential wealth is justifiable.

In the table below are given the important ingredients of some ores and concentrates of the class mentioned.

zinc in the products enumerated constitutes more than 50% of the total in most of the cases cited. Because of the large percentage of zinc present, it has become generally recognized that successful treatment of this class of material depends upon profitable extraction of the contained zinc. This has been accomplished under progressive managements elsewhere, for instance, at Great Falls, Montana; Trail, B. C.; and Park City, Utah. There appears to be no good reason why it should not be done in California, although it will be necessary in each case to meet local conditions by modifications of methods adopted in other places. Many valuable suggestions as to technical procedure in the metallurgical treatment of zincy ore have appeared in scientific publications and patent specifications from time to time. Although any one of the methods proposed may not possess in itself all the requisites necessary, intelligent combinations of features already worked out, coupled with exercise of some ingenuity in supplying deficiencies, will successfully meet requirements at most of the prominent mines.

Complex zinc-sulphide ore or concentrate is not looked upon with favor by metallurgical establishments that purchase custom ore, especially when these materials are in a fine state of division, as, for instance, flotation concentrate. Recently a sample of an ore of this kind from a West Coast mine was submitted to the purchasing agent of a prominent smelting company for a bid. This ore contained approximately 20% zinc, 20% lead, 5% copper, 3 oz. silver, and \$5 in gold. The result was a bid penalizing all the zinc over 8% at 50c. per unit, amounting to a charge of \$6 against the ore in addition to a smelting charge of \$7 per ton. The smelter-value of the copper, lead, silver, and gold was estimated at \$17.50, leaving a total of \$4.50 to the mine-owner for his ore delivered at the smelter. Out of this \$4.50, he would have to pay the cost of mining, freight, and all other expenses. There was nothing unusual about this bid; that is one of the principal reasons why this class of property is not being operated. The smelting company was not taking advantage of the miner; the plant at disposal is simply not adapted to handling complex zinc-sulphide ore to advantage and reduction charges have to be adjusted accordingly. The zinc that constituted one-fifth the weight of the ore in question had to be treated as a liability, not as an asset, and consequently the other metals

Mine and district	Character of sample	Zinc %	Iron %	Copper %	Lead %	Insoluble %	Gold Oz.	Silver Oz.
Anaconda, Montana	Concentrate	30.1	16.1	1.86	9.1	4.7*	0.05	1.35

*SiO₂.

Assuming the prices of lead and zinc to be approximately equal, as they are at present, and that copper is worth double an equivalent weight of zinc, it is apparent from a glance at the table that the invoice-value of the

in the ore were called upon to meet costs due to the presence of an undesirable ingredient. Lead-smelters and copper-smelters do not desire a heavy zinc ore, for the reason that this metal interferes with their established

methods of treatment and occasional losses and additional expense. Zinc-smelters are similarly disposed toward complex ores carrying iron, lime, lead, and other elements that corrode their retorts, or are troublesome to recover at their plants. It is therefore apparent that such ores, or concentrated products, require special treatment by means of which recovery of the zinc in some commercial form is provided.

Writers on the subject have repeatedly stated that zinc requires more chemical or electrical energy, in comparison with its value after recovery, than almost any major metal on the market. With this established fact for guidance, resort to electrolysis as a means of producing spelter should only be made where cheap hydro-electric power is available in large quantity. This method is further handicapped by the high cost of an electrolytic plant and the necessity for pure solutions. However, when fuel is expensive, electric energy may sometimes be employed to advantage for bringing the metals into solution as chlorides. As a given quantity of chlorine will dissolve a greater weight of zinc than it will either copper or iron, the electric energy required for getting zinc into solution under favorable circumstances may be less than that required for leaching copper ore. As to the removal of the zinc from solution, the form of the product desired has an important bearing. In some places simple concentration by evaporation will suffice; much of the ordinary salt of commerce is produced by solar evaporation. This manner of concentrating leach-liquors is not expensive and may be supplemented by the use of roaster-gases or even resistance-coils.

Unfortunately there are no zinc smelters on the Pacific Coast to which zinc concentrate made from complex ore can be sold, and attempts to ship such material to distant metallurgical centres for treatment do not appear to have met with success. Low value of the zinc, heavy deductions from associated metals, and high freight-rates are against the disposal of the product.

From the records of attempts made to treat the complex sulphides of California it is apparent that neither electrolytic treatment of the purified solutions nor concentration by flotation quite cover the situation, but there remain other ways of attacking the problem. Such ore generally contains in itself the essentials for its economic reduction. The sulphur contents of complex ores usually suffice to maintain a roasting temperature in a suitable furnace, with addition of a comparatively small quantity of fuel, and the sulphur di-oxide of roaster-gases has been shown to be an excellent solvent for the zinc oxide in the roasted pulp. Granted these favorable conditions, the expense for chemical energy in getting the zinc into solution is reduced to a minimum. Several methods have been suggested for removing zinc from sulphide solutions, but it is not recalled that any serious attempt has yet been made to apply these methods under Californian conditions. The sulphite method may not be the best for the purpose, but it is mentioned in this connection because in using it the complex ore itself is made to supply the reagent for separating zinc from the metals associated with it. It contains promising features but prob-

ably can be best applied in connection with parts of other processes, adapting the whole conditions which exist in the place where the ore is to be beneficiated. The combination should comprise: (1) utilization of the heat-units produced by combustion of the sulphur contained in the ore itself; (2) application of the roaster gases toward removal of zinc from roasted ore, and for evaporation of solutions; (3) recovery of zinc from solution in the form of salts that have a greater value per pound of contained zinc than the same zinc would have if reduced to spelter.

W. L. AUSTIN.

Riverside, California, May 10.

The Editor:

Sir—Your recent editorial on this subject touches on a subject of vital importance not only to California but to many other localities on the globe where there are ore deposits of similar nature. All metallurgical processes have limitations, and apparently no process has as yet

been worked out which economically and efficiently handles these complex ores containing copper, lead, and zinc, together with gold and silver, be they located in California or in other parts of the world.

I have given the complex ores a great deal of consider-

ation and with the preliminary experiments and investigations which have been carried out in a laboratory in San Francisco, where a 100 kw. electric furnace is installed for experimental work, I believe that these complex ores can be successfully, efficiently, and economically smelted by means of the electric furnace.

The conditions which exist in an electric furnace are different from those which exist in any other type of furnace. The amount of burden present in the furnace at any time is small. Its composition can be changed at will, practically instantaneously, and, by slight modifications in the current and other operating conditions, such changes can be brought about in the furnace that it opens opportunities to the smelting of the greatest variety of ores.

In a general way, the mode which I believe should be followed in an electric furnace for the smelting of concentrates containing the metals would be as follows: By some suitable means, a reducing agent and a fluxing agent would be intimately mixed with the sulphides and placed in a furnace, where, actuated by the high electrical heat, the metals would be reduced. The volatile zinc would readily boil off and at the surface of the charge would burn into zinc oxide, which could be recovered by means of a bag-house or a suitable precipitator. The less volatile metals like copper, lead, gold, and silver, would all be recovered, in pig-metal, which later would be treated according to standard practice and the various metals recovered. Small amounts of these metals might be volatilized and would be recovered with the zinc oxide. These amounts would depend altogether on the operation of the furnace.

The economical way of smelting these ores in an electric furnace would be for the mine to utilize some small water-power in its proximity and in this manner obtain a cheap source of energy for the smelting of the ore. The value of the metals in the ores will determine what price for power a smelter operating an electric furnace can be justified in paying.

I believe that the electric smelting of this kind would foster the economical use and development of many small water-powers now going to waste. As said before, each individual ore would have to be studied and the operations modified according to its composition.

The accompanying sketch indicates in a general way the character of an electric furnace that would be used for the purpose of smelting such ores.

San Francisco, May 1,

J. W. BECKMAN.

Copper and Copperas

The Editor:

Sir—The article, 'Precious Metals in Oil-Shale', by Walter E. Burlingame, which appeared in your issue of May 8, recalls an episode that came to my attention a few years ago. It serves to illustrate the peculiar psychological effect which anything pertaining to mining seems to have upon men who otherwise are perfectly sober-minded.

The ore at a certain mine was supposed to contain

about 3% copper. It was roasted and leached with a solution of ferrous chloride, which was made at the plant by treating a solution of salt (sodium chloride) with copperas (ferrous sulphate). The mine-sampling had evidently been done imperfectly, as the mill-heads ran about 0.65% copper.

About this time, along came Mr. Near Engineer with a line of 'bull' which no mere engineer could hope to equal, and persuaded the directors that the engineers at the property were entirely wrong in their work, and that they were trying to shield themselves by putting copper in the solutions. He happened to see the barrels marked 'copperas' being dumped, and ferrous chloride does have a bluish-green color.

He also actually obtained a grant of \$5000, to demonstrate a process which he and a partner had 'discovered'. With this process, he claimed that he could extract not only the supposedly 3% in the ore, but an additional amount each time he treated the tailing!

To make the story short, the near-engineer turned out to be a bricklayer, his partner a druggist, and their leaching solution, a solution of blue vitriol, copper sulphate.

GEO. O. DESHLER.

Butte, Montana, May 12.

The Matanuska coal-field, in Alaska, is just now of special interest because it is tributary to the Government railroad and because of the coal-mining developments carried on by the Alaskan Engineering Commission. The U. S. Geological Survey has therefore issued, in its Bulletin 712-E, a paper by Theodore Chapin, entitled 'Mining Developments in the Matanuska Coal Field'. Mr. Chapin is in charge of the branch office of the Geological Survey at Anchorage, Alaska, and is actively co-operating with the Alaskan Engineering Commission in the development of these mines. His report is part of the Geological Survey's regular annual account of mining in Alaska and is based on several weeks field work done at different times in the summer and fall of 1918 and on an intimate knowledge of the mining and prospecting that were done in that year. The report includes a brief description of the general geology of the coal-field, a statement of the results of tests and analyses of the coal, a detailed account of the mining and prospecting done in 1918, and descriptions of the geologic features at the mines, and maps of areas near them, as well as many sections showing the geologic relations of the coal-beds. The report is supplemental to the more general accounts of the geology and coal of the Matanuska valley that have already been published by the Geological Survey. The same bulletin contains also a short paper by Mr. Chapin entitled 'Lode Developments in the Willow Creek District', which is the customary brief annual statement of the developments of the year of the gold-lode mines of that district.

The gold output of Rhodesia for February 1920 amounted to £250,020, as compared with £211,851 for January 1920, and £220,885 for February 1919.

The New Modderfontein Mill

*The ore from the mine is removed from the transfer-bin by two 24-in. inclined belt-conveyors, each 193 ft. long, running at 200 ft. per minute, driven by 25-hp. motors with reduction gears and provided with non-rim-back stoppers on the free-wheel principle. The point of delivery into the crusher and sorting-house is situated 38 ft. above the level of the ground. The feature of this section is the thorough washing and the separation and dewatering of the fine by treatment in trommels. The ore first passes to three washing and sizing-trommels, each 5 ft. diam. and 20 ft. long, set at 10° from the horizontal and revolving at 10 r.p.m. The trommels are provided with holes of 3 and 1½ in. diam. The oversize, after being thoroughly washed, is discharged from the trommels to the sorting-belts, of which there are three, each 3 ft. wide and 88 ft. long, running at 40 ft. per minute. Each is driven by a 15-hp. motor fitted with reduction gears.

The undersize from the trommels falls to three screening-trommels, each 5 ft. diam. and 12 ft. long, set on a horizontal axis and provided with internal screw-conveyors. The apertures of the screen are the same as those of the mill-screens. The washed fine is delivered onto a cross-belt, 24 in. wide and 55 ft. long, driven by a 5-hp. motor, and joins the product from the breakers. The products passing through the screens of the secondary trommels by-pass the mill and are classified, the oversize joining the pulp going to the tube-mills; and the undersize is collected in tanks and periodically sent to the cyanide annex, thereby avoiding irregular accessions of water, which are so detrimental to good classification. The six trommels are driven by one 25-hp. motor.

With this system of sizing and washing the following advantages are obtained:

- (1) A clean product for sorting is made.
- (2) Practically no material finer than the mill-screen is fed to the stamps.
- (3) The product is more suitable for belt-conveyance.
- (4) The water-system is confined to the sorting and crushing station only, and the limitations to its use are not governed by the cyanide-annex.

The sorting station itself is particularly well lighted, so that a large proportion of the ore may be sorted. The discarded waste-rock is collected by a number of pipes into bins, and conveyed by endless-belt haulage to the sand-dump. The ore is delivered at the end of the sorting-belts to four No. 6 'K' Gates gyratory belt-driven crushers, each connected to a 60-hp. motor. A fan withdraws any dust produced by these breakers. One crusher is set to the size required for the tube-mill pebbles, the product being screened and delivered by a cross-belt to a storage-bin. From here the pebbles are delivered when

required to the main mill belt and by means of the shuttle-belt to the main storage bin for pebbles, situated at one end of the stamp-mill bins. The main product delivered by the breakers falls onto a cross belt, 3 ft. wide and 138 ft. long, running 150 ft. per minute and driven by a 15 hp. motor with reducing gear. This cross-belt discharges onto the main belt, which elevates the ore to the mill. The main belt is 3 ft. wide, 212 ft. long, runs 150 ft. per minute, and is driven by a 50-hp. motor. The angle of inclination is 16° from the horizontal and the ore is delivered onto a shuttle-belt at the top of the mill, 45 ft. above the level of the ground. The shuttle-belt, 3 ft. wide and 75 ft. long, being driven by a 10-hp. motor, controls the filling of the bins, which have a capacity of 2400 tons. The mill proper consists of fifty-six 2000-lb. Nissen stamps, each set of eight being driven by a 50-hp. motor. The feeders, one to each stamp, are of the fluted-roller type, having the advantage of simplicity of repairs and low cost of maintenance. The plant is capable of a duty of 30 tons per stamp per day through 9-mesh screens. The pulp passes over observation tables and gravitates through two systems of launders to the tube-mill cones, thereby saving pumps in connection with the tube-mill plant. This consists of eight tube-mills, 6 ft. diam. and 20 ft. 6 in. long, the working ratio being one mill to eight stamps, with one in reserve.

The mills are fitted with 5-ft. diam. Schmitt feeders, Osborne liners, and scoop-discharges, and there are arrangements for partitioning a compartment for balls if desired. The tubes are each driven by a 150-hp. motor and run at 28 r.p.m. The main tube-mill cones are 5 ft. diam. by 6 ft. 4 in. deep, and each set of two main cones has a secondary cone 3 ft. 6 in. diam. and 5 ft. deep coupled in series. Pebbles are prepared, as already stated, by one of the rock-breakers and conveyed to a bin at the end of the mill. From here they are carried in front of the tubes on a 12-in. belt, 147 ft. long, driven by a 5-hp. motor at a speed of 60 ft. per minute.

The pulp flows to the amalgamating department, which is arranged as an independent section, in that it is quite self-contained and partitioned from the rest of the plant. A gallery connecting the classification and pump sections with the crushing department runs overhead, and is of advantage in facilitating control, accessibility, and supervision. The copper plates are 40 in number, five per tube-mill; they are erected on angle-iron tables, with provisions for adjusting the inclination. The plates are 5 by 12 ft., with an effective surface of 53 sq. ft., equal to 12 sq. ft. of plate per ton of ore per 24 hours. The amalgam-traps are specially designed to occupy minimum space and are secured by the plate-covers to avoid a duplication of locks. After amalgamation the pulp runs to two 12-in. sand-pumps with a capacity of 1300 tons per hour against a 65-ft.

* Abstracted from pamphlet issued on the occasion of the visit of the South African technical societies to the plant.

100 r.p.m. They are belt-driven from two 150-hp. motors. A sump of ample capacity guards against stoppages in the current supply. The pulp is thus lifted for the first time to a main distributing cone, 7 ft. 6 in. diam., 7 ft. 6 in. deep, and thence to eight classifying cones, 7 ft. 6 in. diam. and 5 ft. deep. These cones are fitted with hydraulic devices and parallel sorting-columns, and the return gravitates back to four tube-mills for re-grinding. Provision is made for operating these four mills either as independent secondary circuits, or on a combination feed of primary and returned material.

The overflow passes to four cones, 7 ft. 6 in. diam. by 7 ft. deep, also fitted with hydraulic devices; these cones separate sand and slime. The position of these cones, quite near the ground-level, is a departure from usual practice—the slime reaching the Dorr thickeners by gravity, while the sand and water gravitate through a concrete conduit to a sump and are then pumped to the sand-plant. At this point comes the mill-water tank, which is remarkable, in that one structure carries the main steel tank, 50 ft. diam. and 12 ft. deep, within which is the cone-classifier service-tank, 15 by 12 ft., the mill-tank being supplied by the overflow from the inner tank, which receives the main supply. The inner tank also supports the Gland water-service tank, 12 by 6 ft. The four separating cones are also supported by this structure.

The sand and water taken as underflow from the separating cones are run to the main pump-house and elevated to the sand-launder by means of 6-in. pumps of 300 tons capacity per hour against a 55-ft. head at 590 r.p.m. These pumps are belt-driven by 45-hp. motors. The tanks are eight in number, 52 ft. 6 in. diam. and 10 ft. 6 in. deep, with filter-bottoms and distributors. The sand is collected and treated without transfer, this being possible on account of the careful classification and the absence of danger from contamination of the mill-water by cyanide. The slime is collected in six Dorr thickeners, each tank being 40 by 12 ft. The tanks are fitted with stirrers and diaphragm-pumps, and the whole arrangement is one of the novel features of the plant. The production of thickened slime, containing 40% moisture with a working ratio of 1:13, solid:water, is continuous, and does away with the periodical sluicing, as is needed in intermittent collecting. The slime runs continuously in launders to the main pump-house, sufficient cyanide-solution being added to fulfil pumping requirements. By means of 6-in. pumps of 300 tons per hour capacity to a height of 55 ft. at 590 r.p.m., the slime is lifted to the

agitators, consisting of six standard Brown, or Pachuea, tanks, 15 ft. diam. by 45 ft. deep. They are arranged and connected to work singly, in series, or in parallel. After agitation the pulp gravitates to a 60 by 12-ft. stock-tank, fitted with stirring gear, and thence to the Butters filter, which consists of 300 leaves and has a capacity of 20,000 tons of dry slime per month. The stock solution is carried at a sufficient elevation in a 40 by 12-ft. tank.

The vacuum in the filter is created by rotary pumps, operating through a vertical cylindrical receiver; discharging of the slime residue is effected by 8-in. high-pressure pumps.

The main pump-building houses all the pump equipment, which is electrically driven. The list of pumps is as follows: three 12 by 15-in. for vacuum; two 11-in. diam. for mill-water; two 6-in. diam. for sand; two 6-in. diam. for slime; two 4-in. diam. for gland-water; two 4-in. diam. for gland-solution; two 3-in. diam. for permanganate; five 6-in. diam. for solution. There are also the following pumps for the filter-plant: two 3-in. diam., valve pressure; two 12-in. diam., slime and solution; two 8-in. diam., high-pressure wash-out; two 8-in. diam., air-vacuum; two 8-in. diam., solution-vacuum; one 6-in. diam., slime-residue; and two air-compressors. The control arrangements for the filter-plant and the whole pumping system, as well as telephonic arrangements, are thus in this one building.

The extractor house possesses no unusual features, the solution passing from constant-head tanks to ten mild-steel boxes, 5 by 39 ft., in which solutions are interchangeable.

The interesting features from the metallurgical standpoint are:

1. Thorough washing and elimination of fine before sorting.
2. Gravity flow from stamps to tube-mills.
3. New design of tube-mill.
4. Isolation without decentralization of plate-house.
5. Continuous slime-thickening by Dorr system.
6. Separation of sand and slime at a low elevation.
7. Flexibility of method of slime-treatment.
8. Collection and treatment of sand in one tank.

The output of diamonds in the Union of South Africa, during the period from July to December, 1919, amounted to 1,383,860 carats, valued at \$34,724,263. October was the most productive month, 264,815 carats, worth \$7,529,147, having been obtained.

The Bunker Hill Enterprise—X

Inner History of the Company: Its Personnel and Its Finance

By T. A. RICKARD

Through all its vicissitudes the mine has yielded a nearly uniform product. The assay-value of the ore has been as follows:

	Lead %	Silver oz.
For 22 years	11.28	4.92
For next 5 years.....	10.06	3.88
For last 7 years.....	10.10	3.92

The Guggenheims made many efforts to get control of the mine. Among these may be mentioned the purchase of the Tacoma smelter, the fanciful salary they paid Mr. Hammond, the continuation of Mr. Bradley as president of the Tacoma smelter, and his appointment as manager of the Federal Mining & Smelting Co., as well as direct negotiations for purchase of stock. When these efforts failed they resorted to apex litigation,⁺ of a persistent and harassing kind, over the Republican Fraction, San Carlos, and Viola claims, their suits being brought through Charles Sweeney, through the Empire State Company, and through the Federal Mining & Smelting Company over a period extending from June 1905 to March 1910. These attempts failed to undermine the title of the Bunker Hill company to its property and were discontinued after March 1910.

The apex litigation in which the Bunker Hill enterprise has been involved is worthy of special consideration. In giving an outline of the successive lawsuits I am indebted to learned counsel, Curtis H. Lindley, who has been the chief adviser to the company. By courtesy of Judge Lindley I am enabled to give a brief but comprehensive review of this phase of the Bunker Hill company's history.

The litigation extended over a long period of years, and involved a number of intricate mining problems, most of which were entirely new and were adjudged in these cases for the first time. The earliest case was what is known as the First Stenwinder, and in order to understand the problems involved in the ultimate ruling made by the courts of last resort, it will be necessary to review the legal decisions prior to that time in suits brought by the former owners of adjoining properties, as the decisions in these cases were of large import in the ensuing adjudications. The judicial status at the time the First Stenwinder suit was commenced may be illustrated by a diagram, Fig. 1.

It will be noted here that there was a small area in conflict between the Tyler and Last Chance, marked A on the diagram. At the time the Last Chance applied

for patent the Tyler company adversed as to this area in conflict, and in a suit to determine the question of priority the Tyler company withdrew its answer and abandoned its right to the ground in dispute, thus establishing, so far as these claims are concerned, conclusively the priority of the Last Chance over the Tyler. In a later suit the Tyler company claimed that the adjudication as to the priority of the Last Chance only applied to the surface, but did not affect the underground rights

FIG. 1

of the Tyler, and that therefore it was at liberty to relitigate the question so far as it affected the underground segments of the vein. This contention, however, was not sustained, and the courts held that the judgment in the adverse suit precluded the Tyler, not only as to the surface, but also as to the underground rights.

About the year 1898 the Bunker Hill company commenced a suit against the Empire State Idaho Mining & Development Co., to establish the rights of the Stenwinder as a prior claim to the Last Chance. The facts involved in this case, and the decision of the courts thereon, are illustrated in Fig. 2.

The trial court limited the Stenwinder extra-lateral right to the south end-line of the Emma prolonged. In this case also there was a small triangular surface conflict between the Stenwinder and the Last Chance, insignificant in area and of no importance whatever so far as the mining claim was concerned, but the Stenwinder failed to adverse and the conflict area was in-

⁺When this was started, in June 1905, Mr. Bradley resigned as president of the Tacoma Smelting Co. and as manager of the Federal Mining & Smelting Co.

the diagrammatic Fig. 6, carving up the segment of the vein as indicated by the conflicting extra-lateral right planes.

The next suit was known as the Bunker Hill Extra-lateral, and was brought by the Bunker Hill company against the Empire State. The Bunker Hill claim was the earliest located in that part of the country, and there was little difficulty in establishing its rights, so the court awarded the extra-lateral right in favor of the Bunker Hill as against all of the claims of the Empire State company.

The last suit between these two companies was based

FIG. 4

upon the Viola and San Carlos, wherein it was sought to invoke the 'jump over' doctrine decided in the second Steinwinder case, as above noted. The extended end-line of these two claims, which are shown in Fig. 3, after passing through the extra-lateral right of the Bunker Hill claim, entered territory that was covered by other locations of the Bunker Hill company, but which were junior in point of time to the Viola and San Carlos, and raised some important questions of geological structure, continuity of orebodies, etc., which would have made it a long battle. This litigation, however, was compromised and the troubles between the two companies adjusted, by drawing vertical boundaries limiting the rights of the Empire State company or its successor, the Federal Mining & Smelting Co., underground, with the provision that after the ore contained in these boundaries should have been exhausted, all the property of the Empire State company or its successor, the Federal company, should pass to and become the property of the Bunker Hill company. It was a long time before the orebodies were exhausted, but ultimately they were, and the Bunker Hill succeeded to all the rights of its adjoining neighbor in the Wardner district.

All the novel principles adjudged in the foregoing cases have remained as precedents to this date, with the exception of the decision in the First Steinwinder case,

which held that a failure to adverse established priority conclusively in favor of a patent applicant both as to surface and underground rights.

In the United States Mining Co. v. Lawson case, 134 Federal, 769, decided in the Eighth Circuit, it was held that a failure to adverse was accompanied with no more serious consequence than the loss of surface conflict area, and that the party failing to adverse was not concluded in a subsequent suit involving underground rights from showing priority. This decision was affirmed by the Supreme Court of the United States in *Lawson v. United States Mining Co.*, 207 U. S., page 1.

FIG. 6

The story of the movement of the different parties locating the Last Chance and the Steinwinder is of special interest. These two parties, the one known as the Flaherty gang, which located the Last Chance, and the other party, headed by S. R. Devine, who located the Steinwinder, approached the ridge on which the mines were situated from different gulches, and the locations

FIG. 5

of these claims by the two parties were in point of time very close together, the actual priority being found by Judge Beatty to be with the Steinwinder by about an hour and a half, after an intensive investigation of the history of the claims, which is referred to in the opinion, 108 Federal, page 189, et seq.

In the earlier days of the mine, particularly during the critical period of 1893, the management viewed the prospects in depth with considerable timidity. It was sug-

ground that winzes be sunk from the Bunker Hill No. 3 shaft to determine whether the ore continued downward. After incurring the expense of driving the Reed tunnel eastward along the lode so as to connect with the Sweeney ground of the Last Chance, which was then in good ore, this lack of confidence in the future of the Bunker Hill caused timidity in the financing of improvements and led to the resignation, as we have seen, of the president and manager of the company.

The map of the mine-workings shows that the ore is distributed in fairly defined bodies, the principal ore-shoot being the original or Bunker Hill shoot, which has its apex at the spot where the lode was discovered in 1885. This orebody has been followed for 3750 ft., on its pitch, which averages 37°. It has a maximum length of 1250 ft., on the 11th level. Eastward the Sullivan ore-shoot has been stoped downward to within 100 ft. from the Kellogg adit; it is irregular in shape, and has a maximum length of 1600 ft. on the 6th level. Some excellent ore has been struck in this part of the mine quite recently.

On the other side, westward, of the Bunker Hill ore-shoot comes that of the Stemwinder claim, the interval between them being 150 ft. They have the same pitch. The Stemwinder ore did not extend below the 600-ft. level, which is 500 ft. above the adit. Then come the Last Chance orebodies, which are regarded by some as a continuation from the Stemwinder, but this is open to doubt. The Stemwinder ore-shoot probably recurs in depth as an enlargement of the Bunker Hill ore-shoot; but it can hardly be considered as a portion of the Last Chance ore-shoot, which in depth is cut by the Cate fault, so that its lower portion should be thrown into the Sullivan ground. The Last Chance ore-bearing ground is 600 ft. long on the strike and reaches as far as the adit, which at that point is 1430 ft. below the surface.

Next is the Tyler ore-shoot. This may be regarded as a continuation of the Last Chance ore westward. It is 850 ft. long on the strike of the lode, and was worked down to the Sweeney level, which is 800 ft. below the outcrop. Thus it may be said that there is an almost continuous run of ore from the Sullivan claim to the Tyler claim, making 5100 ft., or, say, one mile long. Then comes a barren gap of about 1000 ft. before the old Sierra Nevada workings are reached. Here the lode dips south, as compared with the Bunker Hill's dip south-west; the ore is 1000 ft. long and extends for 260 ft. vertically—which is not much. Then, 800 ft. farther north-west, come the later workings in the Ontario and Stewart orebodies, which also dip south. Here the ore was 500 ft. long and was stoped for 400 ft. above the adit. The main Ontario and Stewart orebodies are outside and north-west of the Bunker Hill property, which covers 2920 acres of patented claims, or a length on the lode-channel of 26,000 ft., equal to about 5 miles, with a maximum width of 20,000 ft. or 3½ miles. The mine has 38½ miles of workings. The accompanying map and section show the distribution of the main workings.

The average dimensions of the various ore-shoots, as estimated up to the year 1913, are as follows:

	Length Ft.	Width Ft.
Sullivan	600	18
Bunker Hill	600	35
Stemwinder	600	28
Last Chance	600	51
Tyler	356	14
Jersey	450	24
Francis	400	20

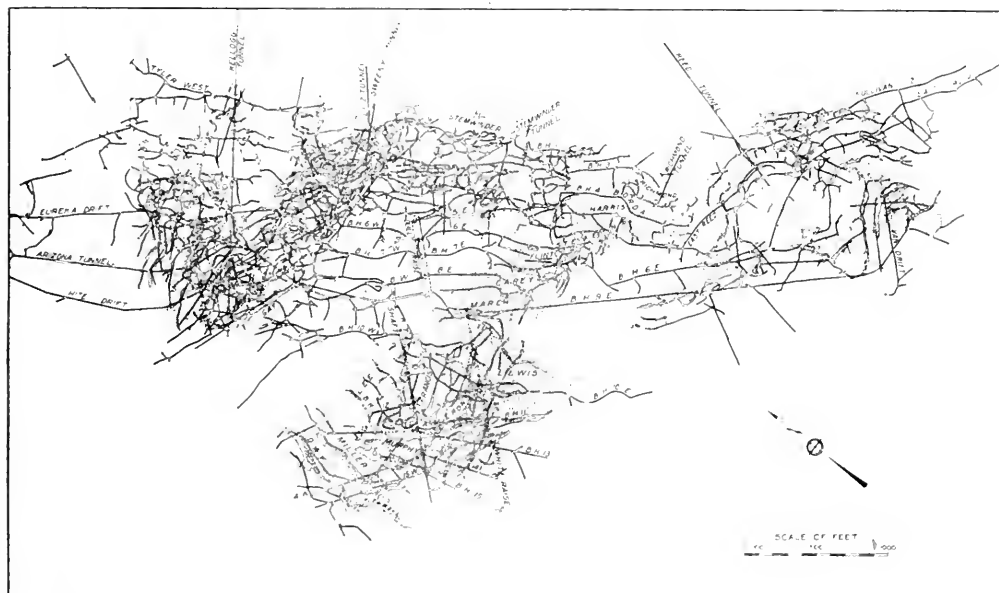

Expressed in terms of production, the output for the first 26 years aggregated 10,250 tons per vertical foot of mining. The average dimensions of the ore-shoots, however, give no idea of their irregular sizes and erratic shapes; looking forward, and deeper, they may pinch in size and they may be cut off by faults, but as against these contingencies there are many other and smaller ore-shoots in various parts of the mine that may increase in size, just as there are dislocated portions of known orebodies to be found beyond the faults already traced through the workings.

The Ontario claim deserves special mention. It became the property of Jonathan Bourne, Jr., of Portland, Oregon, in 1887, on the recommendation of Joshua E. Clayton. Bourne was a plunger; he bought the claim because Clayton (who was called 'Professor' in those days) dreamed that it covered an orebody worth half a million dollars. Mr. Bourne had several chances to sell the Ontario, but he declined them, because he was obsessed with Clayton's idea of its value. In 1908 he decided to bring an apex suit against the Federal Mining & Smelting Co. The Cate fault was then considered to be the foot-wall of the Bunker Hill lode-channel; near this fault no ore whatever had been found in the Ontario or its vicinity up to that time. Bourne demonstrated that the fault crossed the southern side-line of the Ontario and he nearly succeeded in proving that it crossed the westerly end-line, through the north-western corner of the claim; but the Federal company dug away this north-western corner and satisfied the Court that the fault left the Ontario claim through its northern side-line. Thus while Bourne lost his apex fight against the Federal company he contributed to a knowledge of the local geology, so that when F. Augustus Heinze appeared on the scene later and in 1910 uncovered a handsome orebody in the Stewart ground, just north of the Ontario, he (Bourne) was in a position to utilize the information obtained during his litigation with the Federal people. This he proceeded to do, and so successfully that the Ontario eventually yielded a profit of \$1,000,000, from ground within its vertical boundaries that was mined on a faulted portion of the Stewart orebody. Heinze fought hard to prevent the owners of the Ontario from mining this faulted portion of the Stewart orebody, but he lost. So Mr. Jonathan Bourne, Jr., realized Professor Clayton's dream after an interval of 25 years, by which time the Professor himself had gone to the land of shadows.

Looking over the graphic record of the enterprise it will be noted that the dividends soared abnormally in 1906, owing to the sale of the company's 31.34% interest in the Tacoma smelter, which was sold to the Ameri-

LONGITUDINAL SECTION OF THE PRINCIPAL WORKINGS OF THE BUNKER HILL MINE.

PLAN OF THE SAME

The S. & P. S. Securities Co. in 1906, for \$5,079,438.80. The operating profit has varied considerably owing to the fluctuations in the market value of the ore. The tonnage has increased steadily, but the smelter returns have been affected directly by the ups and downs of the metal market. What these have been is shown in the statistics for lead and silver. The cost of concentration has increased, especially in later years, on account of higher wages and more expensive supplies, particularly machinery and machine parts. The increase in dividends is attributable to the combined effects of an increased output, better smelting-rates, a higher price for the metals, together with the additional profit from other sources. The high peak in operating profit in 1917 is linked with the starting up of the Bunker Hill smelter and the abnormal price of lead, due to the War. The wide difference between profit and dividends in 1917 and 1918 was caused by the cost of building the smelter, for which \$2,500,000 has been diverted from current earnings, as well as \$950,000 additional for stocks of custom smelting-ores. How the prices of lead and silver have fluctuated is shown herewith:

Prices of Lead and Silver

	Lead Cents per lb.	Silver Cents per oz.
1888	4.12	94.00
1896	4.18	104.66
1895	3.23	65.28
1900	4.37	61.41
1905	4.707	60.35
1910	4.446	53.48
1915	4.673	49.68
1916	6.858	65.661
1917	8.787	81.417
1918	7.413	96.772
1919	5.759	111.22

In June 11.17c. In December 131.97c.

The relations between the Bunker Hill and various smelting companies are worthy of record. The first concentrate, produced in the mill that was built in Miloguh, was shipped to the smelter, at Wickes, Montana, under contract of 1888 with the Helena & Livingstone Smelting & Refining Co. The next contract was made with Anton Eilers, of the Colorado Smelting Co., at Pueblo. Later the output of the mine went to the various smelters at Denver, Pueblo, Kansas City, Omaha, and San Francisco. In 1898 the Bunker Hill company joined with the Alaska Treadwell group of which Mr. Bradley was president and D. O. Mills a large shareholder, as of the Bunker Hill, in buying 1567 shares out of a total of 5000 shares in the company owning the smelter at Tacoma, on the shore of Puget sound. This stock was bought at the rate of \$100 per share and gave the Bunker Hill a holding of 31.34%; the Alaska Treadwell companies bought an equal interest; certain other friendly individuals also purchased stock, the remaining shares representing the personal holdings of W. R. Rust (the manager of the plant) and a few old stockholders. The smelter was in a dilapidated condition and needed to be reconstructed. The proceeds of the stock-sales went into the treasury of the re-organized company, of which

Mr. Bradley became president, while Mr. Rust continued in charge as manager. Having now an assured supply of lead concentrate from the Bunker Hill mines and an assured supply of gold-iron concentrate from the Alaska Treadwell mines, this smelter was soon placed upon its feet and became such a profitable business that it not only paid dividends after completely rehabilitating its lead-smelting department, but it was enabled, out of its earnings, to add a copper-smelting department. This, the first copper refinery on the Pacific Coast, started to work in 1903. In consequence of its success, the smelter was coveted by the Guggenheims. In 1904 they sent H. C. Davis to Tacoma and he took Mr. Rust back with him to New York. Through Mr. Rust they secured the written consent of Mr. Mills to a sale of the Bunker Hill interest. Early in 1905 Messrs. Davis and Rust, accompanied by Bernard M. Baruch, came to San Francisco in order to complete negotiations. This required several months and resulted in a payment of \$1015.89 per share or a total of \$5,079,438.80 for all the stock of the Tacoma Smelting Co. At the same time, the Guggenheims (in the name of the American Smelters Securities Company) bought control of the Selby smelter at a price of \$4,224,000. The Tacoma and Selby smelting companies were mutually dependent to the extent that the Tacoma lead bullion was being refined at the Selby plant; this inter-dependence was used by the negotiators as a means of searing each smelting company into the belief that the other had sold out. Two years earlier the Guggenheims had acquired the Everett smelter.

One condition in the sale of the Tacoma smelter was that 25-year contracts be made with the American Smelting & Refining Co. for the concentrates produced by the Bunker Hill and the Alaska Treadwell mills, with the proviso that the contracts be revised after the first five years to meet whatever competition might then dictate. Previous to the expiration of the five years, the Alaskan companies created their own competition by building the first unit of a cyanide plant. The A. S. & R. company could not meet the rates as determined by this cyanide mill and consequently lost the Alaskan output. In the case of the Bunker Hill, this company had bettered its contract even before the expiration of the five-year period by establishing outside markets for its +75% lead and its -30% lead products, which the Guggenheims, by an oversight, had excluded from the 25-year contract by covering only such of the Bunker Hill products as assayed between 30% and 75% lead. The concession that had been won as to the +75% product led to investigations in search of a wet process capable of turning out metallic lead and zinc, and this research is still proceeding. It is interesting to note that not only did Curtis H. Lindley and Myron A. Folsom, as counsel, decide that the building of a smelter by the Bunker Hill company was no infraction of the contract with the American Smelting & Refining Co., but Peter F. Dunne, attorney for W. H. Crocker, concurred. Nevertheless it caused litigation. After the concessions won in 1910 there followed a tightening of the Guggenheim smelting control

and the gradual spoiling of the Bunker Hill's market for its +75% and -30% products, in which categories the company was preparing to place the whole of its output. After 1912 the Tacoma company ceased to operate its lead plant, the Bunker Hill output being diverted to the Selby and East Helena plants of the A. S. & R. Co. The dispute with the smelter trust led to the building of a smelter of its own by the Bunker Hill company at the mine. This plant began operations in July 1917, whereupon the A. S. & R. Co. brought suit, the first hearing being set for October 18 at Portland,* in order to obtain a preliminary and permanent injunction against the operation of the smelter at Kellogg. This it failed to do. Eventually, in 1918, this litigation was compromised by cutting the Bunker Hill production in half, one portion to go to the company's own smelter and the other portion to the A. S. & R. Co.'s smelters for the remaining 12 years of the 25-year contract at much better rates than any theretofore obtained.

Rates for freight and smelting on concentrate at various periods during the life of the mine may be compared as follows:

Year	Smelter	Freight and treatment per ton
1886	Helena (Montana)	\$38
1891	Globe (Denver)	28
1894	" "	24
1897	" "	18
1900	Selby (San Francisco)	17
1905	Tacoma (Washington)	16
1908	Pennsylvania (Colorado)	19
1913	International (Utah)	15
1918	A. S. & R.	15

Another interesting phase in the history of such a mining enterprise as the Bunker Hill is the cost of equipment, plant, and other betterments during the entire period under review. Twelve years ago I drew attention to the fact that, as stated in Mr. Bradley's special report of May 27, 1908, to the shareholders of the company, the cost of betterments during 22 years had averaged 80 cents per ton, ranging from a minimum of 43 cents to a maximum of \$3.40 per ton. At that time it was anticipated that an allowance of 30 cents per ton for betterments would suffice for the future. For the 33 years to December 31 last, the following figures are available:

Operating profit	\$30,627,610.26
Profit from other sources	4,213,606.32
	<hr/> \$34,841,216.58
Dividends paid	\$23,231,250.00
Cash and bonds on hand	2,383,933.14
	<hr/> 25,615,183.14
Leaving	\$ 9,226,033.44

This sum of over nine million dollars represents the

*See 'M. & S. P.' editorial, 'American Smelting v. Bunker Hill'; December 1, 1917. Also abstracts of affidavits by Edgar L. Newhouse and F. W. Bradley in same and succeeding issues.

†Variations in Mining Costs', by T. A. R., 'M. & S. P.', July 3, 1908.

cost of equipment, additional mining property, litigation, etc., besides the bare operating costs, or \$1.05 per ton for all expenditures of every kind, in addition to operating freight, smelting, and selling costs. Another tabulation will show the importance of an item usually overlooked when starting a new mining enterprise.

	First 22 years of the property up to May 1, 1908	33 years of the property up to Dec. 31, last
Total tons of ore mined	3,591,880	8,756,536
Gross value of the ore	\$11,060 per ton	\$10.43 per ton
Other income	0.509 " "	0.48 " "
Total to account for	\$11.569 " "	\$10.92 " "
Operating costs	\$2.665 per ton	\$2.61 per ton
Freight and treatment	5.160 " "	4.31 " "
Dividends and cash	2.944 " "	2.92 " "
Betterments and additional mining property	0.800 " "	1.05 " "
Total	\$11.569 " "	\$10.92 " "

During the entire life of the mine, the gross value of the ore recovered has been used up as follows:

	%
Operating cost	25.30
Freight and treatment	41.21
Dividends and cash	28.01
Betterments and additional mining property	5.48
Total	100.00

The 5.48% for betterments and additional mining property, in this last tabulation, is a forced balance to make 100%; but it can be considered as a portion of the cost of these items, the remaining portion of the cost of which can be considered as having absorbed other income, or the profits earned from sources other than from the gross value of the ore. These other sources have been dividends from subsidiary mining companies, for example. Thus while the cost of betterments was 80 cents during the first 22 years, it averaged \$1.05 during the entire 33 years, but this includes the \$2,850,000 diverted from current earnings to build the smelter, plus \$950,000 diverted for the purchase of custom ores, making a total of \$3,800,000, accounting thus for 43 cents out of the \$1.05 per ton, which is reduced thereby to 62 cents per ton.

Mr. Bradley's presidency of the company has synchronized with the period of its successful development. He obtained his technical training at the University of California in 1882 and the two following years, but he did not graduate. Like many men now conspicuously useful and successful he worked his way through college, that is, he met the expense of his education by working during both the college course and holidays. Shortly after leaving the University he made a name for himself by establishing a record for low cost in mining. This was at the Spanish mine, in Nevada county, California. The issue of the 'Mining and Scientific Press' for October 22, 1887, published the following figures. In 22 days of September, 2796 tons of ore was mined at a cost of 37½ cents per ton, of which 32½c. was for labor and 5½c. for

supplies. The mill treated this ore in 20 days at a cost of 23 cents per ton, of which 12.3c. was for labor and 10.7c. for supplies. Thus the total operating cost was 60½ cents per ton; the ore yielded \$1.155 in gold per ton, leaving a profit of 55 cents per ton, or 18½% of the yield. The milling was done with four Huntington mills and amalgamating plates; the ore was quarried from a hill-side, and the labor was performed by Chinese labor at \$1.40 per shift. Mr. Bradley was working the mine under lease after the management had been embarrassed by local debts. The conditions were unusually favorable as to softness of the ore, accessibility, metallurgic simplicity, and cheap labor, but even at that the results were so remarkable as to attract general attention, which, as might be expected, was magnified by the manufacturers of the Huntington mill (the firm of Park & Lacy, in San Francisco). The record made at the Spanish mine was noted in all the books on gold mining of that time. Mr. Hammond heard of the good work done by this young man in the Californian foothills and offered him an engineering appointment at the Bunker Hill in September 1890, and shortly afterward, on Mr. Webb's resignation, made him assistant manager. Mr. Easton graduated from the University of California in 1894. Immediately afterward he worked as a miner in the Bunker Hill mine for several months, obtaining thereby a first-hand knowledge of underground operations. Subsequently he had charge of small mines in British Columbia and Colorado, and in 1902 he was assistant to Mr. Bradley in his San Francisco office. Thus he was well prepared for the responsibilities of manager when in July 1902, upon Mr. Burch's resignation, he was appointed thereto by Mr. Bradley. To the cordial and intelligent co-operation between these two engineers the success of the Bunker Hill enterprise owes much, although both of them are inclined to give the credit to the mine itself.

On the accompanying pages will be found photographs of the principal characters in this interesting story of mining enterprise. R. S. Handy, superintendent of the mills, came from Colorado; he spent one year as a special student in the University of California; in 1905 he entered the employ of the Bunker Hill company as its representative at the Tacoma smelter and in 1906 was transferred to Kellogg, where in 1907 he took up testing and experimental work at the concentrator. In January 1910 he was promoted to the superintendency of all the milling operations.

Walter C. Clark, electrical engineer for the Bunker Hill company, was born in New York and started his career in a drug store at Eureka, Utah; he was early attracted by electrical engineering; in 1895 he operated the electric-light plant of Eureka; in 1898 he was invited by Mr. Burch to come to the Bunker Hill, where he has remained ever since, rising to positions of increasing responsibility.

Gelasio Caetani worked underground and in the mill soon after graduation from the Columbia School of Mines, and finally designed a new mill for the Bunker Hill company. He is a native of Italy and the scion of a noble house, being the son of the Duke of Sermoneta.

Only his closest friends were aware of this fact; he made his own way by sheer force of character and mind. Just before the War he was in partnership with Messrs. Burch and Hershey in San Francisco; when the call came he hastened to Italy and joined the engineer corps of the Italian army, serving with great distinction, and being the hero of the Col di Lana affair on April 17, 1916, on which occasion, as captain of a detachment, he drove a drift 300 ft. long under the Austrians, who were counter-mining; he succeeded in exploding five tons of gelatin and nitro-glycerine under the Austrian position, thereby lifting 15,000 tons of rock and killing 80 of the enemy, besides capturing the 179 survivors, including 9 officers. For this he was decorated. Later he served as a military attaché to the Italian mission at the Paris conference. Talk of romance! the true story of Florence Smith on the one hand and of Don Gelasio Caetani on the other shames the silly yarn about the burro and the prospectors. Truth is stranger than fiction, after all, and far more poetic!

GEOLOGY constantly is being given added recognition as an important factor in the development of oil. The immense growth in the world demand for petroleum and its products is taxing to the uttermost the capacity of the known oil-fields and stimulating the search for new ones. The study of the producing fields is being carried on more and more intensively, not only to learn what contributions may be expected from such new fields as may be found but to maintain the declining production of the old fields and to squeeze the last profitable drop from them. The work of finding petroleum and of producing it is becoming less and less 'a gamble' and more and more an exact science. Geologic work is not only essential to the discovery of new fields but can be profitably continued to direct exploration and production in old fields. For the lack of geologic work different producing beds reached by different wells have been confused during the early life of a field, and the possible sources of water trouble have been overlooked. Men who might have been millionaires have been made practically penniless because they abandoned a well too soon through ignorance or misconception of the true number and position of the oil-bearing beds, and companies well on the road to success have suffered serious reverses by useless expenditure incurred in drilling wells where there was practically no chance of striking oil, and by deepening holes that had already passed through all the possible oil-bearing beds. Entire fields have been abandoned, or almost abandoned, only to be re-opened when applied science or random drilling revealed the existence of oil-sands below the old 'pay'. Other fields have been lost through water trouble due to carelessness, lack of experience, or ignorance of the true source of the trouble and how to prevent it.

SALVADOR is rich in minerals, having deposits of gold, silver, copper, iron, lead, zinc, and antimony. Gold constitutes one of the principal exports. A Canadian company is exploiting the chief gold mines in the country.

THE OLD PLANT ON THE CORTEZ PROPERTY

The Cortez Mine To Be Re-Opened

Special Correspondence

A company composed of mining men from New York and Nevada has been organized to re-open and develop the old Cortez mine, known also as the Wenban mine, situated on the boundary between Lander and Eureka counties, 35 miles south of Beowawe, a station on the main line of the Southern Pacific railroad. The tunnels, through which the mine was worked, are on the south slope of Tenabo peak, in the Cortez range. The mine has produced ore valued variously at from \$13,000,000 to \$19,000,000. The first locations were made in 1863 by Simcon Wenban, who had been grub-staked by Senator George Hearst. Rich float, shown him by Mexican prospectors, led Wenban to the outcrop on the St. Louis group, high on the south side of Tenabo peak. Subsequently he located the 'Arctic', 'Fitzgerald', and 'Gar-

rison' claims and incorporated them in the Tenabo Mill & Mines Co. Ore was hauled to Austin, 65 miles distant, until in 1867 Wenban bought a small mill, with roasters and silver-pans, in Mill canyon, six miles from the mine.

In 1886 he built a 50-ton mill at Cortez, a mile below the mine. The treatment included grinding, heating, wetting, roasting in rotary kilns with salt, sulphur, and lime; and then leaching and smelting with charcoal, at a total cost of \$28 per ton. Lime was produced in local kilns and brick (for building and furnaces) was made at the mine. Mexicans, using as many as 600 pack-animals, supplied charcoal and nut-pine wood for the furnaces, while a 16-mule team was continually engaged in hauling salt, shipped to Beowawe from the Great Salt Lake. An O'Hara furnace was built at a cost of \$50,000, but was

THE MILL AND ROASTER

mine to be useless and was abandoned after a few days. A narrow-gauge railroad, with wood-fired locomotive, connected the mine with the mill. Water was brought seven miles through a two-inch pipe line, still in good repair. For three years, from August 1888, the mine was worked under lease by Bewick, Moreing & Co., of London. During this period the ore averaged 51 oz. silver and \$3 gold, and in three years with silver selling at \$66, dividends amounting to \$671,577 were declared. The main tunnel is in limestone that underlies a wide bed of quartzite. The latter dips 20° north-east and is overlain by another lime stratum. A wide fissure, nearly vertical, cuts but does not displace these strata. The best ore is found in secondary fractures, in the limestone, and in smaller chambers in the quartzite. The main tunnel, nearly 4000 ft. long, follows this vein for a considerable distance and connects with two shafts. Stopes in the limestone are flat and dip with the quartzite, and pillars of rich ore still remain. Visible ore, including dumps and stope-filling, is estimated at 68,695 tons.

A dump containing 5000 tons at the Fitzgerald mine sampled more than 25 oz. silver. Tailing dumps contain 120,000 tons, of which 80,000 tons already has been retreated with a yield of 10 to 14 oz. of silver. This was ground to 20 mesh only, and will be treated again. The Arctic tunnel, driven from a gulch east of, and 300 ft. below, the main tunnel, was advanced 1600 ft. and is to be extended 600 ft. farther to cut the quartzite contact. Fractured ground east of the lower tunnel also will be explored. The ore in some parts of the mine contains lead with not more than 0.5% copper and a little zinc. An operating organization has been perfected and equipment will be provided to drive the lower tunnel and to handle ore and waste from the main-tunnel workings.

THE Mukden district of South Manchuria is generally credited with remarkable resources of minerals, but the present developments are of a limited character. Deposits of coal, iron, gold, silver, copper, lead, asbestos, magnesite, soapstone, and antimony have been reported. Coal is already being extensively mined both by Japanese and Chinese. The former are working large deposits with modern machinery, while the latter are still using crude native methods. The Chinese are planning, however, to obtain modern mining equipment and there will soon be a considerable demand for American machinery. The Japanese are developing large deposits of iron ore. It is estimated that one of their concessions will be capable of supplying ore to their new steel works at a yearly rate of over 1,000,000 tons of ore for 60 to 100 years. The gold is obtained only by placer mining and is not produced in large quantities as yet, although it may be possible to mine on a large scale by improved methods. The magnesite deposits are said to be equal in quality and quantity to any in the world and considerable development along this line is expected, as the world's supply of magnesite is limited and its use is rapidly increasing. Silver, copper, lead, and antimony are not mined in large quantities, and it is doubtful if they are abundant.

Metal-Mine Accounting

Mine accounting including the keeping of costs in mining, milling, and smelting operations has been dealt with often, but mostly with regard to forms for cost sheets, payrolls, time-cards, warehouse requisitions, and other plant forms, without any explanation of book-keeping methods necessary for their compilation, says C. B. Holmes in Technical Paper 250, U. S. Bureau of Mines. He offers the following interesting advice to those who may be starting the development of a new property.

While the articles of incorporation are being prepared or a month before you are ready to start construction, you should employ four persons; first, a practical bookkeeper; second, an experienced warehouse-man; third, a timekeeper; and fourth, a carpenter foreman. Explain to the bookkeeper what the nature of the plant and operation is to be and let him get up a set of books and forms to cover the needs of the plant. Decide on about how much you want to spend on an office building and warehouse, and if your warehouse-man is experienced get his idea as to how the warehouse should be constructed. While the carpenter foreman and his men are building an office and warehouse you will have time to look around for a superintendent or foreman.

To the bookkeeper: after you have found out what the construction and operation program is to be and have formulated a set of books to cover, take the timekeeper and warehouse-man into your confidence and teach them the accounts to which labor and material are to be charged. The accuracy of your books and reports depends solely upon them. You will not have time to follow the timekeeper around and see that he is correctly charging labor, or to see that all withdrawals from the warehouse are properly charged.

This advice is for the engineer in charge: if it has been left to you to decide what detailed costs of construction are to be kept, use a little judgment and do not make the costs so complicated that the whole force will have to be expert accountants in order to properly distribute their time or charge material drawn from the warehouse. I have seen cost schedules devised whereby a carpenter would have to charge his time to one account if he was driving nails into a floor and to another if he drove nails into the wall alongside of him. By following this procedure the construction, development, mining, and other costs will reflect the actual amount of labor and material expended and not contain items prorated from a material shortage discovered after a few months, as is the practice with most mining ventures. During the period of construction and preliminary development the overhead expense can be distributed on the basis of the percentage it bears to the direct expense (labor and material), but after the plant has started operating costs should not be 'fooled' by charging every little item of further construction and changes around the plant with a portion of the overhead expense, as this would probably amount to the same if there were no construction work.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

F. V. X. SELLS ITS EXCESS COPPER.

BISCLE. Operations at the A. B. C. mine, which has been shut down for a month, have been resumed. Drifting toward the Abrigo fault on the 100-ft. level will be the principal work done. Some work will also be done on the 500 and 600-ft. levels. It is also planned to start a tunnel on the R. A. M. group of claims to explore the Ladie claim.

The Great Western Copper Co., at Courtland, is employing 35 men and shipping about 60 tons of sulphide ore per day, and the Leadville No. 1, at the same place, is shipping regularly to Douglas.

The underground workings of the Commonwealth mine at Pierce is being operated by lessees. About $4\frac{1}{2}$ tons of high-grade silver ore said to average 2200 oz. per ton in silver was recently taken out.

The Keystone Copper Co., at Johnson, now has the machinery on the ground for the new 100-ton mill. Construction is to commence as soon as the lumber can be obtained. The Johnson mine has resumed operations and is employing about 65 men. The Johnson Development Co.'s mine is being unwatered after a shut-down of one year.

CLIFTON.—G. J. Stoneman, president of the Stargo Mines Co., announces that the second payment to the owners of the Stargo property will be made about June 1. The Stargo Mines Co. has been developing shipping ore for the past year. The mill-site is being surveyed by the General Engineering Co., of Salt Lake City, preparatory to the erection of a concentrator and cyanide mill. The Stargo are assays \$15 to \$20 per ton in gold and silver.

JEROME.—It is reported that the United Verde Extension Mining Co. has been selling its copper on hand as fast as possible so that only 7,000,000 lb. remain to be disposed of, as against 27,000,000 lb. at the first of the year. In spite of the low prices a good profit has been realized, as the cost of production was less than 10c. per pound.

KINGMAN.—It is reported that the shaft of the Mollie Gibson-Chloride mine has reached the 100-ft. level, where a two-foot vein of galena ore was cut. It is announced by E. A. Ritter, consulting engineer to the Arizona Mossback Mines Co., that the board of directors has agreed to raise \$500,000 by a bond issue for the development and equipment of the mine and the erection of a mill. While cutting a station at the 300-ft. level of the I. X. L. mine

a large body of high-grade mill ore was opened up. It is the intention of the management to cross-cut the vein at the 700-ft. level and drift both ways.

PRESCOTT.—The Golden Dragon Mining & Milling Co., which controls the Emporia group of claims, has acquired the Briganza group on the same ore-zone. A 180-ft. shaft has been sunk and 100 ft. of drifting has been done on the Briganza property. J. Gardner Scott, president of the company, announces that the ground lying between the workings of the two groups of claims is to be prospected immediately. The present five-stamp mill

500-TON FLOTATION-TEST PLANT OF THE NEW CORNELIA COMPANY AT AJIO

on the Emporia property is to be fitted up for testing purposes.

TUCSON.—Los Angeles interests have purchased the holdings of Messrs. Atchley and Hoff in the Arizona Tucson Copper Co. The shaft has been sunk to the 135-ft. level. Twenty feet of rhyolite has been passed through which is stained with iron and contains a small amount of native copper. The company now plans to sink to the 400-ft. level and do lateral development at 100-ft. intervals.

John C. Greenway, general manager of the Calumet & Arizona Copper Co., has announced the purchase of the 85 mine in the Virginia district near Lordsburg, New Mexico, by the Calumet & Arizona. The property has been acquired primarily to obtain silica for the Douglas smelter, but the ore contains some copper and silver. This mine has produced several million dollars worth of ore and it is estimated has half a million tons of low-grade ore developed.

COLORADO

COMPANIES PROVIDE TRANSPORTATION AT CRIPPLE CREEK.

CRIPPLE CREEK. Mining companies will provide transportation to and from the mines, to employees, now that the electric-car line and Short Line steam-road have ceased operating. The Cresson company has provided a special train over the Midland Terminal road for the men on night shift, and it is understood that the Midland company will announce additional suburban service as soon as time-tables are prepared. A miners train, leaving Cripple Creek at 6:50 a.m., is packed to capacity. The Lincoln Mines & Reduction Co. provides auto transportation to and from its Ironclad Hill mine and mill without charge. The Morrell Hardware Co. is running its big auto-truck to Ironclad Hill for the accommodation of miners employed at the Jerry Johnson, Forest Queen, and other mines, without charge, and mine superintendents owning autos are also taking their men to the several properties. In addition to this free transportation, mining companies have announced a 'horizontal' wage-increase for all employees of 50 cents per day.

An electric hoist has been placed at the 900-ft. level of the Empire State shaft, Isabella Mines Co., to be used when sinking of the shaft is started. Six sets of lessees on the property are producing and shipping a good grade of ore from the upper levels. Lessees on the Johnson shaft, Dante Gold Mining Co., have opened up a strong body of one-ounce ore and have commenced shipments to the Golden Cycle mill.

The Lincoln Mines & Reduction Co., it is officially announced, will start concentration of ore at its plant on Ironclad Hill about July 1, when the plant of 400 tons capacity will be completed. The initial treatment will be one hundred tons daily.

OURAY.—Lessees on the Wedge property in the Bachelor district below Ouray are shipping high-grade ore to the smelter from a rich new orebody recently opened. Samples assaying 500 oz. silver are reported from the recent discovery on the El Mahdi, by a leasing company of local men. The vein, five feet wide, is all of shipping grade with richer ore found in two feet next to the hanging wall. In the Lake City section an ore-shoot is reported developed for 400 ft. that is 10 in. to 3 ft. wide, on the Fanny Fern. Shipments packed out and shipped to the smelter have returned from \$60 to \$350 per ton. A pack-train got through the melting snow to the property of the Golconda Mining Co. last week, and operations have been resumed for the season.

LEADVILLE.—The south-western portion of the Leadville district, known as the Silver section, will receive unprecedented exploration this summer. In this territory a number of lessees are already operating and shipping ore is exposed in many old mines that have been idle for several years. In Colorado gulch, claims surrounding the Gertrude are receiving special attention through the opening of rich silver veins during the winter months by the Gertrude lessees. With roads opened, more than 50 tons of high-grade silver ore, stored at the mine in sacks, will be hauled down to the smelter. The main vein under

development at the 120-ft. level of the Gertrude is 3½ ft. wide and assays have shown a silver content of 252 oz. with 2½ oz. gold and 41% lead. North of the Gertrude the Venture, Golden Curry, and Tiger properties, former silver producers, are again active. To the north-west in Little Frying Pan gulch, John Cortellini and associates have operated all the winter in the Keystone tunnel. East and north of Colorado gulch the Dinero and Bartlett tunnels have been operated by lessees this past winter and ore of good shipping grade has been mined in the Dinero. Development on ground cut by the Bartlett tunnel is reported to have been encouraging.

MICHIGAN

WINONA SUSPENDS OPERATIONS.

HOUGHTON.—Fire in the engine-house at No. 3 Kearsarge will interfere to some extent with the production from this branch of the Osceola Consolidated during May. The engine-house was completely 'gutted' and it will be weeks before it will be fit for use. No. 3 shaft is producing the best grade of ore that is coming out of the North Kearsarge. Drifting in progress at the bottom level, the 35th, shows good ground. Power-haulage is in use on the 31st and 32nd levels.

Winona suspended mining operations on May 15. This looks like the finale. The orders from the eastern office not only ordered the suspension, but instructions are to the effect that everything must be taken from the mine that has value. The mine will, therefore, fill with water. If at some later date it is deemed advisable to open the property again the outlay necessarily will be large. From a mining standpoint the decision is regrettable, for at the present time the openings are really in better quality of 'rock' than ever before. The reason for suspension is simply inability to secure the necessary labor to get production large enough to meet the overhead. Winona at best is a low-grade proposition. It does not carry the mass and barrel-copper which has preserved other smaller Ontonagon properties. The history of the Winona has been one of constant hope, large outlay, many millions spent in development, and failure to achieve the desired result. Altogether six shafts were opened and the deepest is 1500 feet. The exploration work has been in the opening of laterals, rather than at depth. Numerous assessments and no dividends are recorded.

Quincy's production of copper for the month of May will not show any increase in total tonnage, yet it will yield between 20 and 21 lb. per ton. This is the best showing the Quincy has made in years. It particularly is gratifying because of the fact that the tonnage mined is below normal. The betterment in the Quincy yield is due more particularly to the improvements which have been made at the stamp-mill, rather than in any change in the situation at the mine or any improvement in the underground conditions. The improvements in the mill, by way of re-grinding appliances, have not been completed, but the saving to the shareholders of the Quincy corporation by reason of these mill changes is substantial.

MONTANA

LABOR SHORTAGE AT BUTTE.

WICKES.—The Atlas mine is to be re-opened and work commenced. Present development consists of a 300-ft. shaft, 800 ft. of drifting on the three levels, and a 100-ft. connecting raise. A reserve of 40,000 tons of concentrating ore, averaging \$12.35 per ton, is estimated between the 100 and 300-ft. levels. Average assays from this ore show 3.2% copper, 12 oz. silver, and 80c. in gold per ton. The equipment includes a 30-ton concentrator and a hoist capable of operating to a depth of 500 ft. The old smelter slag-dumps amounting to 10,000 tons are being loaded for shipment to the East Helena smelter.

Plans for the construction of a 100-ton flotation plant at the Mt. Washington mine have been completed and construction work will commence at once. The mine is one of the largest silver producers in the district. A large tonnage of ore has already been blocked, assuring a good daily production as soon as construction work has been completed. Preliminary flotation tests indicate a high recovery.

HELENA.—The Lump Gulch district now has a number of steady shippers. The Liverpool mine is maintaining a big production of good ore. The Free Coinage is carrying on sinking operations together with keeping up its production. Development work at the Muskegon and Vera Cruz mines continues to be satisfactory.

NEDHART.—The Moulton mine at present is averaging 10 carloads of concentrate and crude ore per week. One car of high-grade ore now in transit is expected to net a return of \$16,000. The output for April has been such as to assure the provisional fifty-cent bonus promised to miners.

BUTTE.—Labor shortage has caused the Anaconda company to close down six of its mines, namely, the High Ore, Mountain Con., Mountain View, Pennsylvania, Belmont, and Tranway. North Butte produced 1,000,000 lb. of copper during April. Development on the 3400-ft. level in the vicinity of the rich Edith May vein is reported as favorable. Assays along the hanging-wall side show 10½% copper for several feet.

The Barnes-King Development Co. reports the following production records for April from its properties; North Moccasin, 1463 tons, bullion yield \$13,000; Pigan-Gloster, 1430 tons, bullion yield \$18,800; Shannon, 2283 tons, bullion yield \$13,800; total, \$45,600.

PHILIPSBURG.—Production in this district is less than 50% normal, due to the tie-up in transportation and drop in the price of silver. The Philipsburg Mining Co. is employing 300 men, less than half of normal. Manganese concentrate is being shipped to Tacoma and San Francisco. The Morelight Mining Co., operating the Headlight and Whitehorse claims, is producing about 18 tons of manganese concentrate daily. Seventy-five men are employed. Since the price of silver went 'tobogganing', 50 of the 125 lessees working silver properties have abandoned their claims, as ore containing less than 25 oz. of silver per ton cannot be profitably mined.

NEVADA

SEVERAL NEW MILLS UNDER CONSTRUCTION.

LUCKY BOY.—A 100-ton concentrator is being built at the Lucky Boy to treat silver-lead ore. The Lucky Boy was found in 1907 and it has produced more than \$2,000,000, mainly from the work of lessees. The Lucky Boy Consolidated, controlled by Jesse Knight, of Utah, drove a 7000-ft. drainage tunnel, cut the vein at 1000 ft., and made connection with a 700-ft. lease shaft. After intermittent production the Consolidated stopped work in 1915 and the mine was again turned over to lessees. The company levied an assessment late last year and resumed work. The lessees shipped rich ore only, and there remains much low-grade material that can be treated at a profit in the new plant. The ore in the dumps is estimated to average \$20 per ton. A new shaft

WORK IN A MICHIGAN COPPER MINE

has been sunk 100 ft. and a cross-cut is being driven to the vein, which also is being opened by cross-cuts from a tunnel. Before work was resumed the claims were added to by the purchase of 20,000 acres, including the Hawthorne townsite. The vein extends into this ground, and before 1915 a drift was driven from the drainage tunnel to the boundary line of the original claims.

ELY.—The 100-ton cyanide plant of the Wyoming Mining & Milling Co. has been started and will be operating at capacity within three months, according to E. P. Bowman, general manager for the company. Eighteen thousand tons of ore in dumps that assays 14 oz. silver and 80c. in gold is to be treated.

SPRING VALLEY.—Two trucks are hauling 150 to 200-oz. silver ore from the Siegel mine to the railroad at Ray, a distance of 20 miles. The Siegel is worked through a 6000-ft. tunnel and there is estimated to be exposed 125,000 tons of ore that assays 20 oz. silver and 20 to 30% manganese. In the American Standard, adjoining the Siegel, a tunnel, now 175 ft. long, is being driven to cut the vein at a depth of 300 ft. The objective should be reached within 100 ft. More than a carload of rich ore is ready for shipment. The El Capitan, a noted silver producer of the early days, also adjoins the Siegel.

IMLAY.—The Majuba Silver, Tin, and Copper Mines Co., organized last fall for further development of the

Majuba Hill mine, is opening, by four tunnels, low-grade copper, silver, tin, and zinc ore. The mine was first leached by the Mason Valley company, owner of the Thompson smelter, and this company shipped to the smelter 2000 tons of 12% copper ore containing $1\frac{1}{2}$ oz. silver. All work in the veins has been done in the upper leached zone and the present work is being done to reach greater depth, with the object of finding persistent shoots of copper ore. There is blocked out 50,000 tons of ore containing 3% copper and 2 oz. silver.

RAILROAD SPRINGS.—The Silver Coin Mining Co. has been organized to develop nine claims on which a favorable report has been made by J. K. Turner, a Goldfield engineer. There are three quartz veins in limestone and shale. The fissures are filled with sulphide of iron and crushed quartz and a distinct clay gouge separates the veins from their walls. The best showing of ore is in a 70-ft. shaft, with 25-ft. drifts on the 50-ft. level, and assays secured by Mr. Turner from these workings indicate that the Silver Coin is an exceptionally good prospect. Ore is exposed continuously from the surface to the bottom of the shaft and in both drifts. The shaft samples gave returns as follows: 2-ft. width, 37 oz. silver, 0.04 oz. gold; 6-in., 37.09 silver, 0.265 gold; 2-ft., 84.02 silver, 0.16 gold; 2½-ft., 78.2 silver, 0.06 gold; 6-in., 111.36 silver, 0.04 gold; 2½ ft., 87.7 silver, 0.1 gold; 6-in., 147.2 silver, no gold, lead 4%. Similar assays were secured in the drifts. The vein averages three feet wide and the best ore is found on the hanging-wall.

STONEWALL.—The Yellow Tiger tunnel at 220 ft. still is in wash from the erosion of a fault scarp, but it is estimated that the solid formation will be entered within 50 ft. Two shifts of miners are employed and two drills are used in the tunnel on each shift. The size of the tunnel is 5 by 7 ft. and in the solid formation this will be increased to 5 by 8 ft. The objective is the Stonewall vein, which should be cut at 1000 ft. from the entrance. Before the Yellow Tiger took over the claims they were developed by a shaft, which showed the vein to be greatly leached but containing good ore. The tunnel is being driven to open the vein well below the water-level.

UTAH

UTAH COPPER REPORT.

SALT LAKE CITY.—The Utah Copper Co. has issued its forty-eighth quarterly report, covering operations for the first quarter of 1920. The total quantity of ore milled was 1,283,300 tons, averaging 1.23% copper, as compared with 1,372,300 tons and 1.25% copper for the fourth quarter of 1919. The average extraction was 86.14%, as compared with 81.56% for the preceding quarter. The total quantity of copper produced was 27,257,546 lb., as compared with 27,965,470 lb. for the previous quarter. The average cost per pound of net copper produced, excluding credits for gold, silver, and miscellaneous income, was 13.20¢, as compared with 16.47¢. The net profit for the quarter was \$2,870,590, and after payment of a dividend of \$1.50 per share the net surplus for the quarter was \$433,855, as compared with \$262,721 for the last

quarter of 1919. The earnings for the quarter were computed on the basis of 21.994¢ per pound of copper; this being due to the sales of copper metal being in excess of production during the period.

PARK CITY.—The mines in this district shipped 2397 tons of ore during the week ended May 15, as against 2227 for the previous week. The Judge M. & S. shipped 718 tons; Silver King Coalition, 553 tons; Ontario, 487 tons; Daly-West, 339 tons; Daly, 108 tons. The Judge smelter shipped 192 tons of premium spelter during the past week. The annual meeting of the stockholders of the Daly-West Mining Co. was held recently at Denver, and the following directors were elected for the ensuing year: Geo. W. Lambourn, Moylan C. Fox, of Salt Lake; O. N. Friendly, of Park City; George G. Brooks, of Scranton; and Harry M. Stonemetz, of Boston. For a supposedly 'worked-out' property, the Daly-West is one of the most active mines in camp, more than 125 men being on the payroll, and this number would be increased if men were obtainable. Recent development work has been satisfactory, as high-grade ore has been opened up. During the first four months of this year the Daly-West earned enough for its full dividend requirements for 1920, after deducting all expenses and taxes.

EUREKA.—H. G. Snyder, manager of the Tintie Paymaster Mines Co., reports conditions encouraging in both the east and north drifts. In the north drift, which is tapping the vein at a depth of approximately 500 ft., he reports the ore to be improving steadily. The cross-cut to the east to cut the main fissure, which shows a width of about 200 ft. on the surface, is now in a little more than 1200 ft., and is in the hanging wall. This is being driven directly into the side of the steep-pitched mountain and gives a vertical depth of more than 800 ft. Two shifts are employed in both parts of the property and the company is pushing the development with all reasonable speed.

Conditions in the Eureka Lily Co.'s winze on the 1640-ft. level continue to improve with depth, according to Grant H. Snyder, the manager. Some recent assays show an average of 46 oz. silver, \$4.60 in gold, and 28% copper. In the drift on the 1840-ft. level, which has as its objective the low-grade orebody encountered near the shaft on the 1640-ft. level, conditions are most promising. Although the drift is at least 50 ft. from the objective, several good stringers of copper ore have appeared in the face, which the management believes are feeders from a mineralized area directly ahead.

WASHINGTON COUNTY.—One of the largest mining transactions in Utah in recent years was made on May 18, when a syndicate represented by F. C. Moorehouse agreed to take over the development of the Silver Reef Consolidated mine at Silver Reef, under an option agreement which permits the syndicate to acquire a controlling interest in the company. The Silver Reef Consolidated comprises the Stormont, Barbee, Walker, and Christie properties, in which it is stated several hundred thousand tons of ore averaging about \$10 per ton in silver is exposed. In addition to this, there is a tailing-dump

which can be treated at a profit. The syndicate will start development in June, and will expend a stipulated sum before it can exercise its right to purchase control. A pilot-mill will be constructed and operated to determine the metallurgical process to be used. The ore occurs in sandstone. In the early days, it is stated that the silver output of these properties totalled between \$10,000,000 and \$15,000,000. As depth was gained in the various workings, copper came into the ore, which introduced metallurgical difficulties that resulted in shutting down.

WISCONSIN

REVIEW OF APRIL.

Operators of zinc mines in the Wisconsin field were disappointed with results during April, because of the industrial conditions obtaining throughout the country. Just as prices for ore of good grade had reached a satisfactory level, railroads laid embargoes that practically prevented some producers from marketing, since most of the ore leaving the field must be handled by connecting lines. Coal became scarce about the middle of the month and the situation was further complicated. The price of high-grade blende opened the first week of the month on a base of \$52 per ton for 60% ore. The second week found large sellers under contract arrangements. During the third week the base advanced to \$57 per ton, on standard commercial ore. On the premium grades, ores assaying above 60% zinc, better prices obtained, some bringing as high as \$60 per ton. This figure declined as soon as the strike began to affect other lines of industry and the base price receded to \$52.50, at which figure it closed the month.

The lead-ore market was well maintained all month, the base for 80% concentrate, at mills, holding steadily at \$110 per ton. Shippers, however, seemed to nurse the idea that the price would go higher and for this reason ore ready for relivity was carried in bins. The strike conditions and the softening of the pig-lead market determined some, at the close of the month, to convert their holdings into cash. Sub-leasing of mineral tracts found favor during the month at several mines operated by the larger concerns, and many small co-partnerships were formed to mine for lead in shallow surface diggings. Unlike the buying in the zinc market, where new interests came to the rescue, lead ore practically remained in the hands of the Federal Lead Co. The reserve in the field is conservatively estimated at 1500 tons, but the ore is hard to find. Carbonate-zinc ore was in good demand all month, but shipments were light. In the northern districts it is said deposits are becoming exhausted and that it is only a matter of a short time before mining will be abandoned. There are a half dozen fine mills in the district now standing idle.

Small lots of iron pyrite were sold from one of the separating plants, but the bulk of this ore recovered at the refining plants was carried along and the reserve runs up into the thousands of tons. The amalgamation of certain steel and black-pipe manufacturers in the

East into a corporation known as the United States Steel & Pipe Co. involves certain corporations in the Wisconsin field. The Vinegar Hill Zinc Co., operators of zinc mines, and the National Zinc Ore Separators Co. have become subsidiary organizations. An acid-plant, built by the Government at New Diggings, has been disposed of by sale of machinery to Chicago junk dealers

MAP SHOWING THE PLATTEVILLE DISTRICT, WISCONSIN

for \$46,000; the buildings were sold to the Wisconsin Zinc Co., and will be used for the storage of zinc ores.

Deliveries of zinc ore and lead ore, for April, were made from mines to refineries in the field as follows:

District	Zinc, lb.	Lead, lb.
Benton	10,246,000	241,000
Livingston	5,825,000	60,000
Galena	2,300,000	64,000
Hazel Green	1,300,000
Cuba City	1,138,000	80,000
Millbrig	932,000	60,000
Highland	780,000
Platteville	750,000
Linden	492,000	62,000
Day Siding	248,000	260,000
Shullsburg	116,000
Totals	24,154,000	832,000

Shipments of the high-grade blende to smelters were made by the following refineries:

Company	Lb.
Mineral Point Zinc Co.	6,100,000
Wisconsin Zinc Roasters	3,554,000
National Zinc Ore Separators	3,398,000
Linden Concentrating Co.	612,000
Block-House Mining Co.	528,000
Total	14,192,000

The recovery of ore at wet mills in the field for the month amounted to 11,887 tons; net deliveries to smelters, 7256 tons of blende and 390 tons of carbonate-zinc ore. The high-grade was distributed among the following buying concerns: Illinois Zinc Co., 772 tons; M. & H. Zinc Co., 205 tons; Grasselli Chemical Co., 998 tons; American Zinc Co., 725 tons; United Zinc Corporation,

99 tons; Prime Western Smelters, 984 tons; Mineral Point Zinc Co., 3050 tons.

BRITISH COLUMBIA

GOVERNMENT ASSISTS DEVELOPMENT OF SALMON RIVER DISTRICT.

STEWART.—The Provincial government, as a result of recommendations made by George Clothier, resident engineer, proposes the expenditure of a considerable sum this year in further opening up the Salmon River mineral area, as well as the zone north of the Portland Canal division. The wagon-road, built last year to the Premier mine, will be continued and trails will be constructed to assist operators and prospectors. In order to make the recording of minerals claims staked in this country easier the whole of the region around the headwaters of the Naas, Unuk, and Iskut rivers has been included in the Portland Canal mining division, so that hereafter prospectors will travel along the line of the Salmon river, making use of the trails referred to, to Stewart to make official record of their claims and assessment work. The section to the south will be administered as before from Anyox, where there is a mining recorder. Previously it was thought to be easier to reach Anyox from the headwaters of the Unuk, Naas, and Iskut than to get to Stewart, owing to the intervening coast mountains.

BARKERVILLE.—L. A. Bonner, manager of the Lightning Creek Hydraulic Co., Cariboo, who returned recently from a business trip to England, states that the season in northern British Columbia in respect of placer mining is extraordinarily backward. A few weeks ago he snow-shoed into his property over four feet of snow and expects that later on trouble will be experienced through freshets. Mr. Bonner looks for an increased output of placer gold from the Cariboo this season, notwithstanding the handicap which the operating companies face owing to the scarcity of labor.

TRAIL.—The development work that has been carried on steadily for some time at the Consolidated M. & S. Co.'s Sullivan mine, at Kimberley, is beginning to show in the weekly ore-shipments that are received at Trail. During the week ended May 7, the Sullivan contributed 10,266 tons of zinc and 489 tons of lead ore toward the total ore-receipts for the week, which were 12,103 tons. The other principal producers were the Josie, Rossland, with 499 tons; Blue Bell, Riondel, 153 tons; North Star, Kimberley, 255 tons; and No. 1, Ainsworth, 114 tons. Peter Dunkerley, who has been in the employ of the Consolidated company for more than 20 years and who for the past 12 years has been purchasing agent, was presented with a gold watch by the office staff of the company on the occasion of his recent retirement.

PRINCE RUPERT.—The Algonian Syndicate has made arrangements with the Canadian Northwestern Railway Co., owners of the Portland Canal short line, to repair the line and utilize it for shipping equipment and supplies to the Fitzgerald group, on Goose creek, which the syndicate has under option. The syndicate has called

for tenders for the repair of the bridges over Bitter creek and Bear river and for several lengths of trestle-work. The Taylor Mining Co. has sent a crew of some 100 men from Vancouver to Alice Arm to replace the men on strike at the Dolly Varden mine and at the railway.

ONTARIO

NEW TRIBUNAL TO SETTLE DISPUTES INVOLVING PATENTED CLAIMS.

A bill is now before the Ontario Legislature for establishing a tribunal to be known as the Mining Court of Ontario, which will have authority to deal with all mining disputes, whether in regard to patented or unpatented mining claims. At present the Mining Commissioner has the power to decide disputes involving unpatented mining claims only. The measure under consideration invests him with the full power of a judge of the County court, and has the cordial approval of mining men and the legal profession of Northern Ontario, on the ground that cases will be determined with less delay and expense than under the existing system.

KIRKLAND LAKE.—The shaft at the Bidgood is now down about 50 ft. on a vein eight feet wide with results stated to be satisfactory. The contract provides for sinking to the 200-ft. level and 2000 ft. of lateral work. The Hulton-Kirkland has purchased mining machinery which will be placed as soon as possible. A right-of-way for power-transmission has been cleared and contracts for supplies are being negotiated. The Jerred group of claims, five in number, with an approximate area of 200 acres, situated south-west of Mud Lake, has been bought outright by the Boston-McCrea interests and work is to be begun immediately. A highly mineralized vein, carrying gold tellurides, has been traced for 200 ft. on the surface and a shaft is down 15 ft. At the Wood-Kirkland a vein upward of 20 ft. in width has been opened in the contact between the quartz-porphory and feldspar-porphory formations. The Harvey-Kirkland, a new company, is operating two claims south-east of the Tough-Oakes and has uncovered several good veins on the surface.

COBALT.—At the middle of May, with quotations for silver having declined a fraction below \$1 per ounce, the question of the possible future trend is the leading topic of discussion in the Cobalt district, where not only the entire community owes its means of livelihood to the silver-mining industry, but where the wage-scale of the mine is based upon the quotations for silver. A point being emphasized, however, is that in the aggregate, the mines of Cobalt produce their silver at a cost of not far in excess of 60c. per ounce. Production from the Kerr Lake mine for April amounted to 61,000 as compared with 99,400 oz. in March. The decline is believed to be permanent, owing to the high-grade ore-shoots becoming partly exhausted, thus making it necessary to treat more medium-grade ore. The plant to treat about 75,000 tons of low-grade ore in the dumps is still under contemplation and a definite announcement may be made within the week.

THE MINING SUMMARY

COLORADO

Breckenridge.—Silver-lead ore assaying 70 oz. silver, in a four-foot vein, has been opened up by Germania lessees. Two earloads of sorted ore were shipped to the Arkansas Valley smelter at Leadville last week. —Local operators have formed a leasing company to operate the Missouri property on Shock hill. The shaft, 50 ft. deep, is to be sunk to 125 ft. to cut the blanket vein dipping into the Missouri from the Iron Mask adjoining.

Clear Creek County.—Operations have been resumed on the Two Brothers mine at the top of Virginia canyon, Idaho Springs. The property was active last summer but suspended operations during the winter months. —In the Georgetown district the compressor-plant at the Sunburst is again in operation and contractors are driving the Astor-Stewart cross-cut to the junction of the Astor-Stewart veins that produced rich ore in the early days of the district. —Erickson & Co., leasing above the Grant level of the Sunshine, has a 25-ton shipment ready to be hauled that is estimated to assay 150 oz. silver and 18% lead.

IDAHO

Coeur d'Alene.—According to reports just received, the Cedar Creek Mining & Development Co. has resumed operations on its property near Murray. A large body of low-grade lead ore was disclosed several months ago. —Development is proceeding on the 200-ft. level of the Chicago-Boston mine, on Lake creek, two miles south-west of Wallace. Samples of the ore opened in the drift are rich in lead and silver. —The Hypotheek Mining & Milling Co., in the Coeur d'Alene, has driven its cross-cut 160 ft. Arrival at a vein is expected at a point 140 ft. ahead where a depth of several hundred feet will be attained.

Moscow.—In co-operation with the U. S. Bureau of Mines and the Idaho Bureau of Mines and Geology, the University of Idaho offers in the School of Mines a number of fellowships, open to college graduates who have had training in mining, metallurgy, or chemistry, and who are qualified to undertake research work. The income of each fellowship is \$900 per year for the twelve months beginning July 1, 1920. Fellows will register as students in the University of Idaho and become candidates for the degree of Master of Science in Mining and Metallurgy, unless this or an equivalent degree has been earned. Their class work will be directed by the heads of the department of instruction, but the greater portion of their time will be spent in research work under the direction of the Bureau of Mines staff resident at the University. The purpose of this work is to undertake the solution of definite problems confronting the mining and metallurgical industries of the State of Idaho. For 1920-'21 the following subjects are being considered:

- (1) Flotation—with especial reference to differential separation of various minerals.
- (2) Treatment of the complex gold-silver ores of the State.
- (3) Ore-dressing problems.
- (4) Mining problems.

Applications, with certified copy of collegiate record, statement of professional experience, and names and ad-

dress of three references will be received up to June 15, 1920. The applications should be addressed to Francis A. Thomson, Dean, School of Mines, Moscow, Idaho.

MINNESOTA

Duluth.—Mining operations on Minnesota Iron-ranges are being curtailed owing to coal shortage, and unless immediate relief comes, mines will be forced to operate with reduced forces and ultimately shut-down to conserve coal for

MAP OF NEVADA

the operation of pumps. Ore shipments from the Hibbing district recently have been less than half of normal. The Oliver Mining Co. has stopped stripping work, and the Shenango Furnace Co. has closed down. Underground work and shovel-operations in the Virginia district have been cut to a minimum. Meanwhile the companies are making every effort to keep men employed and organizations intact. Large numbers of men are working only half time, however.

MISSOURI

Joplin.—A loss estimated at more than \$100,000 was caused by fire of unknown origin that destroyed all of the

principal buildings at the Freehold Oil & Gas Co.'s zinc and lead mine, No. 2, two miles south-west of Waco. The loss was partly covered by insurance. It has not been decided whether or not the mill will be re-built. It was constructed about a year ago and is one of the heaviest producers in the Waco field. The mill had a capacity of 200 tons per day.

NEVADA

Mina. Silver-lead-zinc ore of good grade, containing \$3.20 in gold per ton, has been found in drift No. 615, on the sixth level of the Simon Silver-Lead mine. This is a continuation of cross-cut 603, driven 580 ft. south-westerly from the main shaft to pick up the faulted segment of the principal orebody, which has been thrown by the west fault.

Pioche. At the Prince Consolidated from 2½ to 3 ft. per day is being made in the three-compartment shaft now being sunk to open up silver-gold ore which was found by diamond-drill prospecting. No trouble is being had with water, in fact the work is not developing nearly the flow of water expected so that the pumping equipment in use when shaft operations started has been found to be ample to keep the shaft dry. It is reported that G. E. Bateman after demonstrating in a pilot-mill that he can recover the metal in the Bullionville and Dry Valley tailing, has gone to California to order immediate shipment of machinery and equipment for a 100-ton mill.

The Alps Mining Co. has acquired the Alps mine, one mile east of Pioche, and secured Dan Lloyd as superintendent. The 300-ft. shaft will be repaired and development pushed. The property has produced much good ore and is said to be far from worked out.

Virginia City.—The United Comstock Mines Co. has been incorporated, with a capitalization of \$5,000,000, by Arthur I. Erb, Roy H. Elliott, and Rufus Thayer to operate a combination of properties on the Gold Hill section of the Comstock lode. Stock is divided into 5,000,000 shares, par value \$1. It is understood the Humphries, Jackling, and Bulkeley Wells interests are chiefly concerned in the corporation.

NEW MEXICO

Socorro County.—The work of re-opening the old Colossal Silver mines in the Black range is progressing. The mines have been idle during the past ten years, and the development work is being done by an Albuquerque corporation, which expects to be producing high-grade ore by the first of June. An entire new outfit of machinery has already been placed, and a concentrator will be put in soon.

UTAH

Milford. Steps are being taken to open up the Sheep Rock Mining & Milling Co.'s property, situated in the Newton district, in Beaver county, about 40 miles from here. The property, which consists of ten patented mining claims, embracing 177 acres, is equipped with a 25-hp. electric hoist, air-compressor, and other machinery. The mine in by-gone days shipped ore direct to the smelter, but engineers who have examined it are of the opinion that the ore can be handled to best advantage by the cyanide process.

Alta. Development work has been resumed at the Louise mine, with good results, according to R. O. Dobbs, general manager. A raise from the Maggie tunnel struck a bed of galena, samples from which average from 45 to 61% lead and from 19 to 36 oz. of silver per ton. Another condition which makes officials confident that an orebody will be opened up along the Cardiff contact in the Louise property is that recently in the contact tunnel at a point 600 ft. on the dip of the contact below the ore in the Maggie workings, 20 ft. of vein matter, consisting of lime and manganese-stained lime and clay gouge has been opened up. Since beginning work on the contact vein in the spring of 1918, over 3000 ft. of development work has been done.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

H. Brings, of New York, has gone to France.

Gerald H. Hutton is here from Dayton, Nevada.

L. S. Cates is at the Ray copper mine, in Arizona.

Fred J. Siebert has returned from Arizona to Reno.

Owen F. Brimton, of Salt Lake City, is at Basin, Montana. **Joseph T. Ruth** is returning to Denver from Nacozari, Mexico.

Alma Ek, mechanical engineer for the Braden Copper Co., is in Utah.

H. Kenyon Burch has returned to Los Angeles from Warren, Arizona.

Marshall Bond called here on his way from Santa Barbara to Vancover.

W. W. Mein, of New York, will spend four months at Lake Tahoe, California.

Edwin Higgins has returned from a visit to the Fremont mine in Amador county.

John L. Dyanan, of the Tonopah Extension Mining Co., was in San Francisco this week.

F. M. Jardine has been appointed mill-superintendent for the Butte & Superior Mining Co.

Charles Bocking, manager for the Butte & Superior Mining Co. at Butte, is in New York.

J. C. Emison, treasurer of the A. S. & R. Co., was in Utah recently, visiting the company's smelters.

Harry J. Wolf, of New York, was in San Francisco this week on his way from Arizona to Nampa, Idaho.

Raymond Brooks, formerly of New York, is now with the Union Minière du Haute Katanga, in the Belgian Congo.

F. O. Jasmer has resigned his position with the Cias. del Agwi, S. A., and has opened an office at Tampico, Mexico.

Fred. G. Farish, general manager for the Metals Exploration Co., is in San Francisco. He will spend several weeks in California.

E. DeWitt Burlingame, in charge of the welfare department of the Braden Copper Co. at Rancagua, Chile, is at Salt Lake City.

D. D. Moffat, consulting engineer of mills for the Jackling companies, is visiting the Ray and Chino mills in Arizona and New Mexico.

Byron O. Pickard, recently appointed district engineer of the U. S. Bureau of Mines, with headquarters in San Francisco, has been spending a week in Utah.

H. K. Armstrong has resigned from the Liberty Bell Gold Mining Co., Telluride, Colorado, to go to the American Silver Corporation, at Mogollon, New Mexico.

George H. Garry will become consulting engineer to the Tonopah Divide company on June 1. At the same time **William Waters** will resume his position as superintendent of the mine.

E. P. Mathewson spent several days in Salt Lake City recently on his way to Anxox, British Columbia, where he expects to remain several months. On May 10 the Colorado School of Mines conferred upon him the degree of Doctor of Science.

At its annual meeting on May 19, the Utah Society of Engineers elected the following officers: **H. T. Plumb,** president; **LeRoy Pharis,** first vice-president; **E. H. Beckstrand,** second vice-president; **W. E. Turner,** secretary; **R. K. Brown,** treasurer; and **L. J. Seckles,** member of the executive committee.

F. E. McDonald, millman for the North Idaho Metals Co., at Kellogg, Idaho, was instantly killed on May 11.

THE METAL MARKET

METAL PRICES

San Francisco, May 25

Aluminum dust, cents per pound	65
Antimony, cents per pound	10
Copper, electrolytic, cents per pound	19
Lead, pig, cents per pound	8 7/8
Platinum, pure, per ounce	895
Platinum, 10% iridium, per ounce	\$130
Quicksilver, per flask of 75 lb.	\$80
Spelter, cents per pound	9 1/2
Zinc dust, cents per pound	13.00-15.00

EASTERN METAL MARKET

(By wire from New York)

May 24—Copper is inactive but steady. Lead is quiet and firm. Zinc is inflexible and lower.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2, on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 6, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 40 1/2 pence per ounce (925 fine), calculated at the normal rate of exchange.

MONEY AND EXCHANGE

Francis H. Sisson, vice-president of the Guaranty Trust Co., sees danger in forcing too rapid deflation. He is quoted as saying:

"The chief danger in the present situation is that the desirability for low prices as an end in itself may be so exaggerated as to lead to the attempt to force prices down through harmful measures for the control of credit. The notion seems to prevail that the war-time and post-war rise in prices was on the whole disadvantageous to the country. Prices moved up irregularly with consequent maladjustment, some individuals gaining while others were injured by the changes. Even when it is granted that resort in some degree to measures tending to raise prices was necessary during the War, it is thought by some that the evils incurred by the rising prices may and should now be matched by the supposed benefits of falling prices. Those who look merely at the mechanical aspects of the exchange of goods find so much money and credit on the one hand secured against so much of goods on the other—with prices expressing the ratio between the two. Accordingly, the desired lower prices may readily be obtained, it is thought, by arbitrarily reducing the volume of money or credit, especially the latter. Such action has been repeatedly advocated.

"There seems to be no question that undue speculation should be curbed by restricting further the credit employed in such undertakings. Beyond this, however, there is a distinct danger in attempting arbitrarily to reduce general prices by curtailing credit to business undertakings. It is to be remembered that such credit is the outgrowth of business demands. It is not as if a given volume of credit should exist independently of business needs, forcing itself upon an unresisting business public. The proper function of the credit machinery is to adjust the volume of credit to the actual needs of legitimate business. Accordingly, the influence determining the credit sought and granted should have their initiative in the field of industry and trade. If the control of credit is such as arbitrarily to fix the volume of credit extended to business undertakings, it may, indeed, succeed in lowering prices of goods already produced and consumed—namely, as one line of production largely absorbs and utilizes the products of another, and since the curtailment of credit tends to a slackening of business activity, but there is no assurance that the lessening of industrial output occasions the necessary reduction in the actual state of demand and the needs of the business community.

"The urgent need for wise leadership in the handling of our industrial and financial problems is not a matter concerning only our domestic affairs. We are confronted now with the unique opportunities for the development and strengthening of our position in world enterprise. There is promise of a coming period of rapid development of the newer regions of the world, the storehouses of the principal natural resources upon which the industry and trade of the future will largely be based. The more easy and natural we can make the necessary readjustments in our industry and finance the better able we shall be to share in the benefits of the prospective period of expansion. Elsewhere such opportunities are being recognized and utilized.

"It is significant to note that, despite the present handicap of adverse exchange, the volume of British foreign trade is rapidly approaching our own, and Great Britain still has the largest merchant marine, and London is still the financial centre of the world."

Foreign quotations on May 25 are as follows:

	Demand	3.85 1/2
Francs, cents:	Cable	7.23 1/2
	Demand	7.55 1/2
Lire, cents:	Demand	5.55 1/2
Marks, cents:		2.73 1/2

Eastern Metal Market

New York, May 19.

All the markets are still under the blight of the transportation muddle but prices in most cases are steady.

Demand for copper is still light but quotations are firm.

Heavy buying of future-shipment Straits tin has continued but spot Straits is scarce.

The lead market is dull with the price-range indefinite.

There is still no life to the zinc-market and prices are easier.

Antimony is a little lower.

IRON AND STEEL

Reports indicate little improvement in the shipping situation, but hopeful signs, wanting a week ago, point to an early resumption of railroad traffic, says 'The Iron Age'. With the immediate cessation of the strike it would take six to eight weeks to recover the operating pace of March. The present natural stagnation in business is not accompanied by any softening of prices as would normally occur under such a condition for, besides full order-books, a slump in buying will be offset by the necessarily gradual resumption of the mills. There are 1,300,000 tons of finished products in yards and warehouses in the Pittsburgh district alone and the leading interest has probably 600,000 tons of unshipped material, and in the whole country the undelivered manufactured steel is not far short of 2,000,000 tons.

Premiums are disappearing, partly because inability to make prompt shipments removes the chief reason for their being. Pittsburgh is operating at about 75% of ingot capacity, while Youngstown is at less than 50%. Shipments of semi-finished steel have been rather heavier, in proportion to other forms, than usual.

COPPER

The transportation situation is probably the most important factor in this market and its evil effects are apparent. It develops that some of the large refiners are facing a depletion in their supply of crude copper from smelters, many tons of this being held in transit at the railroads. Some drastic means have been necessary to obtain needed supplies in some cases. The same is true of shipments of refined metal on contract. Raw material and finished copper are not moving freely and unless an improvement develops speedily it may be necessary for some refiners to shut-down. This matter is also serious from a credit or financial point of view and is causing concern. The net result is that consumers are not free buyers and only small amounts of Lake or electrolytic copper are being sold. Quotations of leading producers are firm at 19c., New York, for both electrolytic and Lake copper for May-June delivery, with 19.25c. asked for delivery in the third quarter. In the outside market quotations range from 18.50 to 18.75c., New York, for both grades of copper with but little available.

TIN

Sales of future-shipment Straits tin have continued on a large scale, the total since May 10 having been over 700 tons. This with the 1100 tons sold the previous week, brings the total recent sales to at least 1800 tons. On May 11, sales were light at 75 tons; on May 12 the total was 125 at prices ranging from 55.50 to 56.25c.; on May 13, they were 425 tons at 53.87½c. for July-August shipment, to 54.75c. for April-May shipment; and on May 14 they were 100 tons at 54.75c. for May-June shipment, to 55.25c. for June shipment. These transactions were mostly among dealers although consumers participated to some extent; they were also made on the New York Metal Exchange. There appears to be a shortage of spot-Straits tin which today is quoted at 54.75c., though it has hung around 56c.

most of the week, where it has appeared to be pegged. An evidence of the shortage of Straits tin is the fact that on an inquiry sent to London for June arrival here, this grade of tin was reported unobtainable. This shortage will result in a demand for other grades. There has been a good business in Banca tin which has sold at 2 to 3c. under the price for Straits. On Monday, this week, inquiry has been fair with the market quiet. The London market yesterday was £302 per ton for spot Straits and £287 for spot standard tin, an unusually wide spread, and a further illustration of the scarcity of the former grade. Arrivals thus far this month have been 2745 tons with 4670 tons reported afloat. Tin ore arrivals thus far this month have been 3675 tons.

LEAD

The market has again taken on a mixed character. Buyers seem to have lost courage and are inclined to let the market alone. Some sellers are 'whistling to keep up their courage'. The price-range appears to be a wide one with some interests talking 9.25c., New York, for lead in the first half of June, while others have offered the metal down to 8.50c., New York, in some instances. We quote the market at 8.15c., St. Louis, or 8.50c., New York. The leading interest maintains its quotation at 8.25c., St. Louis, or 8.50c., New York.

ZINC

This market continues lifeless and uninteresting. There are no developments except a slight easing in values. Prime Western for delivery into July is quoted at 7.70c., St. Louis, or 8.05c., New York. Sellers are not interested at these levels and demand from consumers continues light.

ANTIMONY

The market is quiet with the better grades quoted at 9.75 to 10c., New York, duty paid, with lower-grade material obtainable at 9.50c., New York, both in wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, for early delivery in wholesale lots, is quoted at 33c., New York, from the leading producers, with 31.50c. asked by other sellers.

ORES

Tungsten: Freight congestion in New York has adversely affected a market already 'in the dumps'. As a result almost no business has been done. Prices are nominally unchanged at \$7 to \$15 per unit in regular concentrates, depending on the grade. Imports of tungsten-bearing ores in March were 217 tons of which 100 tons came from China and 44 from Chile. Total imports for the nine months ended with March 31, 1920, have been 4961 tons against 9961 tons for the same nine months a year ago.

Ferro-tungsten quotations are unchanged at 85c. to \$1.15 per lb. of metal in the alloy or the powdered metal.

Molybdenum: This market is also dead with quotations nominal at 75c. per lb. of MoS₂ in regular concentrates.

Manganese-Iron Alloys: Except for active requests from consumers for shipment of ferro-manganese on contract there is very little change in this market. Prices are the same as a week ago. A large Philadelphia producer will soon start a furnace which is expected to produce 2500 tons per month and another in June which will make 2000 tons per month. It is rumored that two large steel companies plan to produce the alloy in the near future. A producer of ferro-alloys by means of electric furnaces in Alabama will soon produce ferro-manganese, it is understood. Spiegel-eisen is strong but only moderately active at \$75, furnace, at which some sales have been reported.

Company Reports

NIPISING MINES COMPANY, LTD.

Report for the year ended December 31, 1919.

Property: mine and mills in the Cobalt district, Ontario.

Operating Officials: R. B. Watson, general manager; Hugh Park, manager; James J. Denny, manager of the research department.

Financial Statement: gross settlements for the year, \$4,941,791; value of custom ore purchased and inventory of December 31, 1918, \$2,282,818; gross value of 1919, Nipissing production, \$3,752,083. Cost of mining and treatment, \$1,083,251. Net income from 1919 production, \$2,717,312. Net profit, \$2,776,250. Net surplus December 31, 1919, \$4,372,952.

Dividends: during 1919, \$1,800,000, making total to date \$20,940,000.

Development: The amount of underground work done during the year was about the same as in the previous year, notwithstanding two months shut-down during the strike. Development work was more satisfactory than in 1918, because of the good results obtained on veins 99 and 109, and on the extension of 73 vein at the third level. Exploration, that is, the search for ore in new territory, made up 70% of the total advance. The older veins, after sending 48,361 tons to the mill, show a decrease of only 12,802 tons.

A summary of the remaining ore-reserves follows:

	Tons	Assay, oz.	Content, cz.
High-grade ore	2,896	1373.0	3,976,774
Mill ore	113,165	20.9	2,377,882
Total	116,061	54.8	6,354,656

Production: shipments of silver amounted to 3,080,069 oz. The costs are computed on a basis of 66,202 tons of ore produced, of which 962 tons was treated in the 'high-grade' mill.

SILVER KING CONSOLIDATED MINING CO.

Report for the year ended December 31, 1919.

Property: mine and mill at Park City, Utah.

Operating Official: Harry A. Lee, consulting engineer and assistant manager.

Financial Statement: receipts included \$62,248 from sales of ore, \$128,200 from convertible notes, and \$46,600 from sales of stock. Total, \$341,742. General expense, \$58,316; development and mining, \$58,873; tunnel account, \$103,814. Total, including miscellaneous, \$308,755.

Dividends: no dividends during 1919. Total to date, \$1,562,705.

Development: present activity is confined largely to the development of the Silver King ore-zone by means of the Spiro tunnel.

Production: 780 tons of crude ore containing 24,608 oz. of silver and 443,652 lb. of lead, and 572 tons of concentrate containing 9,412 oz. of silver and 299,292 lb. of lead was marketed.

ALASKA JUNEAU GOLD MINING CO.

Report for the year ended December 31, 1919.

Property: mines and mills at Juneau, Alaska.

Operating Official: P. R. Bradley, general superintendent.

Financial Statement: revenue from bullion, \$400,644; from concentrate sold, \$142,070; total \$542,714. Operating and development expenditures, \$702,303; construction and other expenses, \$355,776. Total expenditures, \$1,058,079. Balance sheet shows a deficit of \$563,625 on December 31, 1919.

Dividends: none to date.

Development: 10,814 ft. of advance was made during the year, the work being confined to the North orebody, chiefly in preparation of No. 410 and 420 stopes. The plan of

'waste rejection' was further developed and at the end of the year one-third of the rock delivered to the mill was being rejected. This material assayed less than the mill tailing. Reconstruction of the mill, designed to reduce costs and increase capacity, progressed to the point where 8000 tons can be handled. The final capacity will be 16,000 tons per day of rock from the mine, of which one-half will be rejected as 'coarse' tailing by sorting. Additional mine equipment will be necessary to handle this output.

Production: 673,421 tons of ore was stoped; 19,474 tons came from development work; 616,302 tons of fine ore was milled. The ore averaged \$1 in gold; 64c. per ton was recovered as free gold, and 18c. per ton was realized on galena concentrate.

MIAMI COPPER CO.

Report for the year ended December 31, 1919.

Property: mines and mills in the Miami district, Arizona.

Operating Officials: F. W. MacLennan, general manager; J. H. Hensley, Jr., mine superintendent; F. W. Solomon, mill superintendent.

Financial Statement: actual profits after taxes, but before depreciation and depletion, were \$1,582,701. The company reserved \$295,695 for depreciation and \$1,806,748 for ore-depletion; surplus of current assets over current liabilities at the close of the year amounted to \$6,939,990, as compared with \$7,146,093 at the end of 1918.

Dividends: during 1919, \$1,867,785; total to date \$21,-462,829.

Development: work to the amount of 14,552 ft. was done, made up of 12,937 ft. of drifts, 1587 ft. of raises, and 28 ft. of shaft-sinking; 75% was for the purpose of preparing for, and maintaining, ore production from the main orebody by the undercut caving system of mining which was introduced in this orebody during the year. New development during the year resulted in very slight changes in the boundary of the high-grade orebody, and estimates place the tonnage of this class of ore at 11,054,349 tons of an average grade of 2.38% copper. There was very little churn-drilling done and this was confined to the low-grade area, consisting of completing hole No. 117 for a depth of 469 ft.; 36,000,000 tons of an average grade by drill sampling of 1.06% copper is reported in reserve, in addition to 6,000,000 tons of mixed ore averaging 2%.

Production: 1,698,466 tons of ore averaging 2.04% of copper produced 65,544 tons of concentrate averaging 43.54%, with a mill extraction of 82.38%. The total refined copper produced was 54,221,638 lb., amounting to an average monthly production of 4,518,470 lb.

MINING CORPORATION OF CANADA

Report for the year ended December 31, 1919.

Property: mines at Cobalt; the Cobalt Reduction Co.'s mill and the Buffalo mines.

Operating Official: M. F. Fairlie, resident manager.

Financial Statement: revenue from sale of bullion \$1,-411,184, which with sundry income made a total of \$1,689,-996. Total cost \$735,724; net profits \$954,272. Surplus on December 31, 1919, \$3,311,577.

Dividends: during 1919, \$622,519.

Development: the total ore-reserve is made up of 15,716 tons carrying 440,275 oz. in place, and 23,019 tons carrying 866,945 oz. of broken ore in stopes and on dumps. An increase in both tonnage and silver content over the previous year is shown in reserve, this new ore having been largely developed in stoping operations. During 1919 the corporation continued its general activities and its search for mining properties.

Production: the total tonnage was 63,904 tons, the total ounces recovered being 1,230,653, of which 72,193 oz. was from high-grade ore.

Book Reviews

Technical Writing. By T. A. Rickard. Pp. 178, index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$1.50.

It is appropriate that T. A. Rickard should have written and that the house of Wiley should have published this practical volume of hints and inspiration for those who seek to express clearly, accurately, incisively, the information they would convey to the world. Whatever is worth doing at all is worth doing well. We ordinarily send for the carpenter when we would build a book-case; some of us possess the skill to build it creditably ourselves. Everyone of us should be able to do so, because the elemental trades, in their elementary stages of development, should constitute part of the training of men who would be adequately equipped for civilized life. Expression is also a trade, common to all men, though in varying degree. Like the hammer and saw, simple primal tools of everyday life, words are the instruments for driving our ideas into the understanding of other men. Instinctively man turns away in annoyance from a botched job. That is why most of us take no chances of ill-matched boards in a book-case, but send for the carpenter. The new generations, schooled in sloyd, will be able again, as were our great-grandfathers with their wide culture in the fundamentals of life, to make the book-case themselves.

Even an old dog may be taught new tricks if his interest be sufficiently aroused, for educating dogs and men is mainly a question of inspiring the learner so that his attention is absorbingly concentrated upon the things presented by his teacher. It is in the light of this illustration that the value of Rickard's 'Technical Writing' is to be estimated. Being himself as remote as the Himalayas from the literary sin of 'fine writing', save when done with that open self-consciousness that transmutes it into humor, he sets up no standard that may weary or affright any person who would acquire a more finished technique with the simple tools of verbal expression.

The character of the book is as unpretentious as that remarkable series of Bendigo papers which first gave the mining profession warning that there had occurred a happy conjunction in Rickard of a technologist and a writer of the first order. He had a message; he knew how to deliver it. Such skill as that is not to be attained by all. It is not necessary, however, to be an art-craftsman, to be a good and capable carpenter, able to make something that is both acceptable and pleasing, even without citing the high cost of living as an excuse. The thing that any man, having a common-school acquaintance with Lindley Murray's elements, can learn to do with Rickard's 'Technical Writing' is to avoid making a botched job of his commitment to paper of the ideas he would express. The first and foremost thing, of course, is to have something to impart, and every man engaged in the practical business of mining ores and smelting metals from them has acquired some knowledge that is not common property. Each individual's experience holds something that is original, that is just as new and different as his face is different among all the millions of men on the planet. Civilization advances by recording these fresh bits of knowledge, and he who does not record his, thereby cheats the world of its due. We owe it to our fellows who have written for us, to write for them and for those who come after, so as to make easier the way to success in the solving of their daily problems.

Looked at in this practical light, the preparation of this admirable manual on the art of writing is of special personal importance to the profession, individually and collectively. One may not all at once apply every precept in the book, but its perusal will serve as an intellectual uplift, as a stimulant, as a mental clarifier. The need of such a

treatise is very great at this moment of general decadence of the English tongue. The universality of minor culture has produced so vast an audience of moderate comprehension that the newspapers and magazines vie with each other to exploit that huge body of readers, because it offers a profitable field, wherefore the most powerful periodicals of the day are allowing crass commercialism to drag them to the level of those who do not know and who care less for the correct English that has served so many distinguished generations of American and English statesmen, savants, and scientists, as a vehicle for transmitting logical thought for the progress of mankind. Confusion of speech and confusion of ideas are handmaids, and lead to slovenliness and error, not only in the teaching of science but in the promulgation of political doctrine.

Rickard quotes, as a textual justification for his book, that interesting and pungent criticism of James Barrie: "The man of science appears to be the only man who has something to say, just now—and the only man who does not know how to say it". For this alone the writing of the manual would have been warranted; but its scope is broader than the scientific field; it deals with the theory and practice of expression, which is equally vital to the economist, to the politician, to the banker, and to the man of commerce. All of these have something to say nowadays, and they are saying it in so uncertain and ambiguous a manner that the multitude knows not which way to turn for deliverance. The deluge of false social doctrine that has bewildered our world is very justly traceable to a confusion of ideas, as seen in the failure to express correctly the distinction between capital and a form of accumulated profit submerged by investment, of which the German high priest of socialism was guilty. We need clear thinking and clear writing in these days, and the fundamental condition for both is an understanding of the correct use of language.

It is this broader value of the book, gauged by the need of accurate expression by workers in every walk of life, that commends it especially at this moment. The details, as suggested by chapter headings, 'Naturalness', 'Clearness', 'Precision', 'The Relative Pronouns', 'Prepositions and Preposition-Verbs', 'Hyphens and Compound Words', 'Style', and many more, are not those of the usual treatise on English composition. The work is as distinct in its class as the author's Bendigo papers were different and more stimulating than any other treatise on gold mines ever written. It is in the spirit of that sane French school of literature that demands straightforwardness, accuracy, and a holy abhorrence of those vagaries of style that are carelessly mistaken for genius. His basic formula, the touchstone of his every decision concerning proper usage in writing, so elementally sound as to win universal approval, is "Remember the Reader". This is the reduction of expression to its most valuable democratic function, for reaching and informing the people. One does not need to be uncultured to speak appealingly to the uncultured. The highest test of culture is the ability to employ simple terms that cannot be misunderstood by the multitude. 'Technical Writing' will prove an invaluable aid in learning how to speak directly to the point, how to recognize and weed out unsuspected errors, in diction, and the use of words that cloud the meaning.

Courtenay De Kalb.

The Book Department of 'Mining and Scientific Press' has issued a 72-page catalogue of books carried in stock in San Francisco. These publications cover a wide range of subjects in various branches of engineering and technical activity, the list being especially complete in books dealing with mining and metallurgy. A summary of the contents of each book is given, and there are indexes by authors and according to subjects. A copy of this convenient catalogue will be mailed to those interested upon request.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE BLACKSMITH AND GOOD DRILL-BITS

By D. E. Dunn

Manufacturers of rock-drilling machinery can and do make good rock-drills and drill-sharpeners. However, they can never eliminate the personal equation of the blacksmith. It would seem that the most uninformed persons would realize that the success in rock-drilling is almost entirely dependent on the blacksmith turning out good steel. While the drill-steel sharpener has gone a long way toward improving the quality of bits, even with improved machines, proper bits cannot be made without care and judgment on the part of the blacksmith.

The Ingersoll-Rand Co., manufacturers of rock-drilling

ENGINEERING FOUNDATION SEEKS ENDOWMENTS

Based on the generous gifts and high purposes of Ambrose Swasey, Engineering Foundation has since 1915 maintained a liaison between engineers, as represented by the Founder and other societies, and scientific workers, as represented in National Research Council. Practical means for co-operation in research have been set up so that engineers in the numerous branches of the profession may join with physicists, chemists, geologists, and others in the attack upon problems of common interest and in the exchange of knowledge.

Although engineers, like other professional men as a class, are not wealthy, some individual engineers have large

Some Results of Four Blacksmithing

machinery, recently had a complaint that one of its Jackhammers was falling down on the job; in the customer's own words, "the drill didn't have any pep". One of the company's representatives investigated this case and the accompanying photograph shows the actual condition of the bits that were used in this mine. The bit shown in the centre was made by this representative with the same machine as the other four bits shown, demonstrating clearly that it was not the fault of the sharpening machine. Is it any wonder that the Jackhammer didn't have any pep?

It is found that a large number of complaints can be traced directly to bad blacksmithing, against which the manufacturers are waging a continual campaign of education. Such complaints illustrate the problems that the representatives of mining machinery companies are frequently confronted with, that is, dissatisfaction of sincere but not thoroughly informed operators.

means. Engineering Foundation seeks to build up its endowment to dimensions worthy of the profession. Engineers connected with industrial and financial organizations having great resources can aid by convincing proper officials of these corporations that the continued prosperity of our industries depends upon continued progress of research. Since the commercial and industrial establishments of the country reap the larger proportions of the financial profits arising from scientific and technological work, these establishments should contribute liberally to the support of research.

Engineering works, public, corporate, and private, frequently involve studies of special problems or in themselves constitute full-sized experiments, which could be made to yield important data for general technical use. Sometimes the engineers in charge do not perceive the opportunity, not having been trained in research work. More often the possibilities are realized, but means, men, and time are not

available because of the urgency for completing the project with a minimum expenditure in the shortest practicable time. Occasionally experimental work is undertaken in accordance with a well-conceived plan as a necessary or desirable adjunct to the main operation. In such cases the exigencies of the main operation sooner or later interrupt the experimental work; or the men who have it in hand leave the force; or the information is gained, but never written up; or the statement is buried in some report of limited circulation; or greater familiarity with research methods and a broader conception of the problem could, with small additional expense, have secured much more valuable results and have made them more generally useful.

The services described in the foregoing paragraphs, and many others could be performed by Engineering Foundation, if adequate funds could be placed at its disposal. The Foundation does not plan to build laboratories and conduct research work directly, but rather to stimulate, co-ordinate, and support research work in existing scientific and industrial laboratories, co-operating, insofar as may prove advantageous, with the National Research Council.

Charles F. Rand, 71 Broadway, New York, past-president of United Engineering Society, and of the American Institute of Mining and Metallurgical Engineers, was elected chairman of Engineering Foundation on March 19. With the collaboration of Mr. Swasey, Mr. Rand is actively seeking additions to the endowment fund which will swell the total to at least a million dollars in the near future. Mr. Swasey's gifts amount to \$300,000. The office of Engineering Foundation is in Engineering Societies building, 29 West 39th street, New York. Further information may be had by addressing this office or the chairman. A booklet giving an account of the Engineering Foundation and its work will be mailed upon request.

CLIMBING HILLS AT PACHUCA, MEXICO

The steepest grade in Mexico used for commercial purposes is 'El Bordo', a road approximately two miles in length and running on the edge of a mountain to the El Bordo silver mine, operated by the Santa Gertrudis company at

The Old Mines of Pachuca

Pachuca. The road referred to has an average grade of 14½% with two stretches each exceeding 19%, and is replete with sharp difficult turns. It was on this road that the Duplex 4-wheel drive truck demonstrated its hill-climbing-plus-hauling ability a few weeks ago. On the first morning the truck was loaded with two tons of cement, and made the top without difficulty. The load was increased on the second trip to the total carrying capacity of 3½ tons, and the run was completed with equal facility. The mining company then suggested that an even larger load be tried, and, although it was a clear case of overloading, 8630 lb. of cement was placed on the Duplex and carried to the top of the hill apparently as easily as the first load of two tons.

The ascent was made in 44 minutes. Upon arrival at the top the radiator was sufficiently cool to allow bare hands to be placed on it without discomfort. The spring deflection with the 4-ton load was 1½ in. on the front, and 3 in. on the rear.

Accompanying the data pertaining to the 'El Bordo' demonstration is a table describing the profile of the road, furnished by C. A. Lantz, manager of the Santa Gertrudis. Space does not permit its reproduction here, but a reading of it reveals grades actually as high as 21%, and approximately twenty curves in 7886 ft. of road traversed. This table—a copy of which can be obtained upon request—proves that every care was exercised to obtain absolute authenticity in every phase of the demonstration, and that Duplex performance was out of the ordinary. A further demonstration was effected for the Real del Monte on its steepest grade. This is a mountain road, nine miles long, with grades ranging from 4 to 14%. The load carried was four tons of iron balls and the trip was made without incident, except for passing another 5-ton truck with a 2-ton load.

COMMERCIAL PARAGRAPHS

At a recent meeting of the board of directors of the Wellman-Seaver-Morgan Co., John A. Penton, president of the Penton Publishing Co., was elected a director to fill the vacancy caused by the death of Samuel T. Wellman. Mr. Penton's intimate knowledge of the iron and steel trade, his wide acquaintanceship with prominent people in all lines of industry in this and many foreign countries, and his keen insight into business matters will make him a valued co-worker on the board.

The Booth Electric Furnace Co., Chicago, reports a number of additions to its sales and engineering staff. B. G. Tarkington, formerly industrial heating engineer with Hodenpyl-Hardy Co., is at the Chicago office in charge of district sales. The Buckeye Products Co., 919 West 5th St., Cincinnati, who has charge of sales in the Cincinnati territory, has placed D. E. Carpenter, formerly of the Detroit office of the Westinghouse Electric & Manufacturing Co., in charge of sales of Booth furnaces in that district.

The Bridgeport Brass Co. makes all its brass in electric furnaces, and in this development it has been a pioneer. A recent attractive book describes and illustrates in detail the art of brass-making dating back hundreds of years, leading up to the most modern practices as in use in its plant, including the electric casting-shop. The important steps in the making of tubes, sheet, rods, and wire are also shown. It discusses the properties of brass as affected by composition, cold-working, and heat-treatment, with the idea of assisting engineers in drawing specifications. In the compilation of this pamphlet the company has deviated from the conventions and traditions of the brass industry by making an open book of the practices and processes of brass making and the result is an interesting and valuable publication.

The Dodge Sales & Engineering Co. distributes the products manufactured by the Dodge Manufacturing Co. and the Dodge Steel Pulley Corporation. Its recent catalogue 'D-20-Chain' is believed to be the most complete and comprehensive publication obtainable on the subject of 'Industrial Chains for Elevating, Conveying, and Power Transmission'. The book is compiled and arranged for the convenience and benefit of the engineer and of the operator. No attempt has been made to list a complete line; but rather to show the various types and their general application in various kinds of service. The principles of design, the choice of material, and the conditions of operation are detailed, and the specifications necessary in the purchase of this class of equipment are discussed. The catalogue is a valuable handbook.

T. A. RICKARD. . . . Editor

WE continue to receive propaganda on thrift and the buying of Liberty bonds from the Savings Division of the U. S. Treasury Department. Have these gentlemen no sense of humor? How can their solicitations be effective so long as the Treasury Department continues to carry 38,000 employees on its payroll and wastes paper, which is expensive now, on lucubrations that no one reads? What is the use of recommending Liberty bonds when they are allowed to fall below 90, after being described emphatically as the premier investment security in the world? Gentlemen, set an example of thrift by ceasing to squander the national income.

UNDER 'Positions Wanted' there appears an advertisement from a mining engineer offering his services as a flying-man to any mining company needing one like himself. Our young friend saw service with the Army and has read in the daily papers that aeroplanes have been used to reach remote mines, in Alaska and elsewhere. We await with interest the result of his offer. Meanwhile we note the issue, by the U. S. Bureau of Mines, of a paper on the 'Use of Airplanes in Mine-Rescue Work', by Mr. F. J. Bailey, who concludes that they can be used to advantage for this purpose in regions, such as the Middle West, where the surface is comparatively level.

NO recent appointment to an important administrative position seems to us to be so entirely satisfactory as that of Mr. John C. Merriam to the presidency of the Carnegie Institution, in succession to Dr. Robert S. Woodward. Dr. Merriam is dean of the faculties and professor of paleontology in the University of California, but he has been serving for some time as chairman of the National Research Council, in which capacity he has proved his keen intelligence and high character. As a splendid exponent of the highest ideals in American science, it is most appropriate that he should be placed at the head of the Carnegie endowment, where we hope he will find an unfettered opportunity to stimulate research of the most useful kind.

IT is well to get the point of view of others. We are glad therefore to publish a speech by Mr. Francis A. Govett on the status of gold, as reported in the columns of the 'Financial Times', of London. On the occasion of this public utterance Mr. Govett was presiding at the annual meeting of the Ivanhoe Corporation, a company owning a famous gold mine at Kalgoorlie, in Western

Australia. In London Mr. Govett is the leader of a mining group with which Mr. Hoover used to be connected; he is a gentleman that takes himself pretty seriously, but he succeeds in winning the attention of serious people, and he has won deservedly a reputation for sagacity and integrity. His remarks on one of the principal problems of the day are well worthy of respectful consideration.

SENATOR PITTMAN has performed a public service in correcting a misapprehension in regard to the purchase of silver by the Mint. It has been stated in sundry papers that the Mint will accept only fine silver under the Pittman Act. This is incorrect. The Mint will accept ordinary bars of bullion as they come from mills and smelters, as it has done heretofore. If the bullion contains a one-thousandth part of gold, it is then regarded as a deposit of gold; and the silver in a gold deposit, no matter how small or large it may be, is paid for at the rate of one dollar per ounce for each ounce therein contained of so-called pure silver, that is, 1000 fine. If the bullion contains no gold, but contains 601 thousandths of silver, it will be accepted as a silver deposit and be paid for in the same way. The expression used in the Act, "one thousand fine", measures the price paid for the silver in bullion, but does not control the purity or kind of bullion receivable by the Mint. A small charge, for parting the silver from other metals, is made, as is usual at the smelters. The Director of the Mint has issued instructions in accord with this interpretation of the Pittman Act. Under the misunderstanding it has been charged that only refiners could obtain the benefit of the Act. This is quite wrong; on the contrary, under the Act it becomes unnecessary to send silver to the smelters and refiners.

CONGRESSMEN continue to flirt with the soldier bonus. Flirtation is defined as attention without intention. Everybody at Washington knows that nothing will be done in this matter during this session of Congress, but the various proposals seek to catch the vote of the soldiers in the coming elections. The Government is piling up a deficit of three to four billion dollars per annum, besides three-quarters of a billion into railroad losses and half a billion into Shipping Board expenditures, not to mention two-thirds of a billion as interest on the public debt. This is no time for further extravagance, which only belittles and commercializes the services of our brave boys. It is time the politicians stopped

fooling them. On May 19 the Secretary of the Treasury declared his opposition to any bonus legislation, "however financed". He stated that it would be "highly unfortunate" if any new obligations were placed upon the Treasury, and suggested that it would be wise for Congress to seek out additional sources of revenue to meet current government expenses.

SIBERIAN gold is the subject of an editorial in the "Morning Scream". It discusses the effect of finding gold "in quantities" in north-eastern Siberia, particularly as a stimulant to Japanese aggression. The reported discoveries, it is said, would suffice "to change history in this part of the East, as gold finds have changed history elsewhere, beginning with Colehis". The range of classic lore exhibited by this reference is impressive, but the editor would have done better to substitute the North Fork of the American river or the Yuba. It might have been less grand, but it would have been more significant. We are told by him that north-eastern Siberia is "not an attractive country to stampede into". It is not. "There are no towns, no roads, no bases of supply." That is profoundly true. "The existence of placer gold on the Siberian side of Bering strait has long been known." Yes; a similar statement can be made concerning the gold in the sea. "Placer mining is not a game that lends itself to poaching." It is, if the gravel be rich enough; but, as has been recorded in these columns many times during the last twenty years, the evidence available indicates that the alluvial deposits of Nome do not extend across Bering strait and that north-eastern Siberia is not a country rich in gold.

GOOD citizens, without distinction of party, must regret the unseemly squabble between Admiral Sims and Secretary Daniels. The washing of dirty linen in public is never an edifying performance. We note, however, one remark by the Secretary of the Navy that deserves to be remembered. He describes Admiral Benson as "all-American, neither 'pro' nor 'anti' with reference to any other country". There he struck a true note of genuine patriotism. In times of peace the less appeal is made to prejudices against European nations, the better it is for genuine Americanism. A propaganda either for or against a foreign country has a disintegrating effect on the national spirit, particularly of those who themselves or whose parents came from across the sea, because such appeals are addressed to feelings that are non-American. The bitter anti-British propaganda of the Hearst papers has a bad effect, not only because it stirs up ill-will toward a country with which we have many friendly ties, but because it evokes the sympathies of one group and the antagonism of another group, provoking enmity between them and forcing an alignment upon non-American issues, thereby hindering the process whereby those of foreign birth are developing into true Americans. The great problem of the United States is the absorption of its alien elements into a composite nation in complete sympathy with its own traditions.

That process is hindered every time that various groups among our people are asked needlessly to take sides in a controversy involving the country of their origin or its neighbors.

WE are informed that henceforth a geologist is to be attached to the San Francisco office of the U. S. Geological Survey, in collaboration with Mr. Charles G. Yale, who has charge of the statistical work of the local office. The Director of the Survey plans to increase the usefulness of his bureau to the Pacific Coast, including Nevada and Arizona, by this innovation. The duty of the new appointee will be to visit promptly any recently discovered mineral deposits in these States and to revisit the more important of the older districts as often as is practicable; it is proposed also to have strictly geologic data on tap in a manner corresponding with the statistical and other information that Mr. Yale has been furnishing for years so courteously and efficiently. This, of course, is not meant as an encroachment on the field of the State Mining Bureau of California or the analogous bureaus in the other States; the resident geologist of the Federal Survey will supplement, not duplicate, the work of the State organizations; he will co-operate with them whole-heartedly. It is known to the friends of Mr. Yale that he will be seeking retirement before long; he has earned a rest, but the Survey is loth to let him go, and it is extremely desirable in the public interest that his work should be lightened and that he should be enabled to give the benefit of his accumulated experience to a younger man before seeking the leisure to which he is entitled. We hope that this new move will postpone that event, for the Survey office without Charles G. Yale would lose much of the character that has made it valuable and attractive to those engaged in mining on this Coast.

WALKERVILLE is a victim of circumstance, according to the irreconcilables who have made their homes in the little town for more than a generation. Except for the accident of its situation just around the hill from Butte, Walkerville would be a thriving town today, as it was when Butte was merely a row of shacks inhabited by a few miners who washed gold from the diggings that fringed what afterward became known as Anaconda hill. Later when Butte, on account of its more favorable site, began to grow, the Alcie mine at Walkerville was the mainstay of its industry. The story is told how John Noyes, owner of sundry real estate, received a tip from Marcus Daly, who was in charge of the Alcie. On this particular occasion when Noyes waylaid him in order to learn, confidentially, the latest development in the mine, Daly mournfully shook his head, whereupon Noyes, assuming that the future was not rosy, sold a corner lot at the intersection of Main and Broadway for \$12,000, and tried in vain to dispose of other property. As a matter of fact, Daly had been joking with his friend, for the next day the report of the finding of a wonderful new vein was made and Butte real estate began to boom. The story goes that Noyes would not speak to Daly for a

year. The silver ore in the Alice, the Lexington, and other mines was remarkably rich, and for years these mines thrived and Walkerville flourished with them. Then came the collapse in the price of silver, and the subsequent closing of practically all of Walkerville's mines. Much of the population left, but the town itself survived. It still elected its own mayor, and had its own lodges and its own clubs. The sons of the earlier generation walked over the hill to the Speculator, the Badger, the Elm Orlu, and the Black Rock; they went to Butte to spend their money, but they still lived at Walkerville. Now the Moulton, the Goldsmith, and the Alice are showing the effect of high-priced silver; they are the scene of active mining. Lessees are at work, in shallow surface pits, on old dumps, and in the underground workings. Everybody seems prosperous. But Walkerville is handicapped by propinquity to the country's only 'mining city'. Every 20 minutes an electric car toils slowly up the hill and symbolizes the bonds that make it impossible for the old town to rouse from the lethargy of three decades.

The Mexican Melodrama

Another act is over; exit Carranza. The grim play of Mexican politics is sometimes a farce, but always ends with a tragic note. In the dark hours of May 21 the seventy-second Mexican government in 99 years came to a bloody finish when Venustiano Carranza was murdered by traitors in his own camp at Tlaxcaltenango, when making an effort to reach the coast north of Vera Cruz. It may be well to recall the other acts in the Mexican melodrama, which, like a Chinese play, seems to be a continuous performance. On May 25, 1911, Porfirio Diaz resigned as President of the Mexican republic and fled to Europe. He had ruled the country for 34 years and was 81 years old. Francisco Madero, the leader of the revolution, an amiable reformer, was duly 'elected' President. On February 22, 1913, he and Piño Suarez, the vice-president, were assassinated by the soldiers of General Victoriano Huerta, who became President. A new revolution was started by Carranza, then Governor of Coahuila, to avenge the death of Madero. The opposition to Huerta was joined by Francisco Villa, a bandit of the dirtiest type, but a good fighter. Villa defeated Huerta at Torreon. Carranza assumed the title of First Chief of the Constitutionalist Party and finally succeeded in driving Huerta out of office and out of the country in July 1914. Three years later Huerta died a natural death, but not in Mexico. The victor assumed the presidency, only to find his government flouted by Villa, Zapata, Orozco, and other insurrectionary chiefs. On September 23, 1914, Villa declared war on Carranza and drove him out of Mexico City to Orizaba. Then Alvaro Obregon came into prominence as Carranza's best general; at the battle of Celaya, in which he defeated Villa summarily, he lost his arm by shell-fire. Thanks to Obregon, the power of Carranza was consolidated and on October 19, 1915, the government of the United States recognized his administration

as the *de facto* government of Mexico. On March 11, 1917, Carranza was 'elected' President. Already he had shown pro-German sympathy, and the publication of the Zimmermann note, which just preceded the declaration of war against Germany by the United States, indicated clearly his unfriendly attitude to this country. He endeavored to prevent the production of oil in the Tampico district and issued a series of decrees harmful to American interests in Mexico. When his term of office approached its legal end, this year, he attempted to dictate the election of Ygnacio Bonillas, formerly Ambassador to the United States, as his successor. It was claimed by General Obregon and other candidates for the presidency that Bonillas was a mere deputy, meant to occupy the office while Carranza retained control and prepared to make some shift that would return him to power. When about to be arrested by Carranza's orders, Obregon started a revolution, which broke out first in Sonora under the leadership of General Elias P. Calles. On May 8 Carranza fled from the capital in a vain effort to reach Vera Cruz, but was blocked by troops under General Pablo Gonzales, who then joined the new revolution, which found general support all over Mexico. Two weeks later the dead body of the First Chief was brought back to Mexico City and buried among the poor in the Dolores cemetery. On the same day General Adolfo De la Huerta became President *ad interim* and postponed the presidential election from July 4 to September 5. Meanwhile General Gonzales withdrew his candidacy, so that General Obregon became the acknowledged leader of the successful revolution, which, like a primary election, marked him as the head of the seventy-third government since Mexico gained her independence from Spain in 1821.

So much for the sombre side of the story. Now comes a celebrated writer, Señor Blasco Ibañez, and develops the humorous aspects of this moving picture of graft and murder, politics and pillage, bombast and brigandage. In the Spanish novelist's scenario Venustiano Carranza appears as a frockcoated *ranchero* of dignified mien, with a flowing beard and a smattering of law, the country gentleman *muy simpático* of his friends, the *viejo barbon* of his enemies, and the 'Don Pomposo' of the caricaturist. He rose to power by making use of the military leaders and he fell when he quarreled with them over the spoils. First Villa and Angeles, then Obregon and Gonzales refused to play the old man's game, leaving him for Chief of Staff a military Adonis, 'Juanito' Barragan, remarkable for his sartorial splendors and a graceful hospitality to ladies of the stage. Carranza's nominee for the presidency, the ambassador, Ygnacio Bonillas, was made known by an extravagant campaign of posters and his nickname, *Flor de Te*, the Tea-flower. Pancho Villa, a murderous blackguard, a butcher and a brigand, has had his side-show of fighting and looting while the other *dramatis personae* have occupied the centre of the stage. Occasionally he interrupts the main action of the play. The scholarly Felipe Angeles is caught by the Federal troops and dies a gallant

death with his back to the wall. Don Pablo Gonzales, prudent and respectable, watching which way the cat jumps, an opportunist in *excelesis*, quits Carranza at the critical moment and assures the success of the revolution. Not caring to endanger his skin, he declines to compete with Obregon in the 'election' that is to give formal sanction to the recent *bouleversement*. Alvaro Obregon is a veritable cinematic hero, a gallant soldier minus an arm, a flamboyant orator, a picturesque *paseur*, the logical victor in the topsyturvy of militaristic misrule. Good-naturedly wicked, brutally gay, and rustically frank, he twirls his upturned moustache and smiles upon the scene, which, at the moment, looks fair to him. The chick-pea dealer of Sonora enters the palace of Montezuma. *Viva Obregon!*

Concerning Gold

Many queer notions prevail in regard to the price of gold, despite the efforts of technical and other papers to inform the public on the subject. Bankers and public men of responsible character have tried to dissipate sundry fallacies that stick like burrs in the minds of the average man, yet the old yarns survive apparently with unimpaired credibility. For example, we have received no less than four copies of a "keynote address" that was to have been delivered by Colonel Chester T. Kennan before a New Gold Standard Convention at Spokane on May 19. Whether this address did prove the keynote to the projected convention we do not know, but we deplore the waste of good paper at a time when a shortage of that product is so acute, particularly as the gentleman who squandered it for the purpose of personal publicity is not one whose opinions on an intricate problem are such as to merit confidence. His address is as full of glaring blunders as a sieve is full of holes. "During the last five years", he says, "gold has not been in circulation as money or medium of exchange in any part of the world." This is not true; there has been a plethora of gold as a medium of exchange in several countries, notably Norway and Holland, not to mention the United States, where gold is still performing its customary function. The Colonel—where did he get the title anyway?—asserts that "we have no common measure or standard of value now, all nations have suspended or repudiated gold payments". This is contrary to fact, as can be ascertained by anybody who will take the trouble to do so. If, for example, the Colonel desires to turn \$10,000 into gold, he can obtain from his banker a draft on a Federal Reserve bank for that amount, and the Federal Reserve bank will give him the equivalent in gold coin. The Federal Reserve bank is not compelled to do this, but it will pay him in Federal Reserve notes, which the Treasury at Washington must redeem at par, as is printed on the notes themselves. Next the Colonel makes the statement that "no government dares to pay out its gold now at the old standard price per ounce". The Government of the United States will sell gold to Mr. Kennan or anybody else at the rate fixed by law, namely, \$20.67 per ounce. That is exactly what jewelers and other

manufacturers are doing every day. The Mint, however, according to law, does not sell gold in the form of bullion in amounts less than \$5000 at a time; similarly the Mint will buy bullion in amounts of over \$50, these restrictions being matters of convenience. The Colonel says that what we need is an "honest" dollar; he asserts that our dollar should be "stabilized". He will find that the American dollar is today the most stable monetary unit in the world and that other units are being measured in terms of it. Next the Colonel talks a lot of nonsense about the ex-Secretary of the Treasury and a "swindle" perpetrated by the "McAdoo syndicate". Mr. Kennan has the habit, as we are aware from communications received and rejected by us, of making wild statements reflecting upon the honor of public officials, such as the heads of Federal departments. He has written a lot of drivel concerning the U. S. Treasury in his "keynote" address and he ought to be ashamed of it. Next we note that he claims acquaintance with a broker "who was recently hired by a Seattle firm to buy placer gold in the Blue Mountains district at \$33 per ounce, and the firm was to give him \$2 per ounce commission for buying it, which would make it net the firm \$35 per ounce". What is still more strange, the broker failed to make his purchases because "other buyers, of whom there were a dozen or so in the district, were paying around \$35 per ounce". This is pure buncombe. His broker friend can buy gold from the U. S. Mint for \$20.67 per ounce, and he can sell it to the Mint for \$20.67 per ounce. The notion that gold is selling for \$35 per ounce anywhere is a mare's nest. If Mr. Kennan sends his gold to London he will obtain for it 107 shillings or thereabouts, the price varying daily. This price, as compared with the normal of 84.95 shillings per ounce, will represent a premium of about 20% in *shillings*. When he returns to New York and turns his shillings into *dollars*, he will find that he must pay a discount equal to the premium he received in London; in other words, the premium on gold measures the depreciation of British paper currency in terms of American dollars. When gold is selling at 107 shillings, the pound sterling is exchangeable for about \$3.85, instead of the normal rate of \$4.86. Mr. Kennan asserts that the banks are "selling the people's gold coin to foreign countries at about \$35 per ounce and pocketing the profits, i. e., all over \$20.67 per ounce". This silly talk is followed by a similar statement that "the smelters of the United States have been and are paying the miners of smelting ores only for 95% of the gold contained in their ores and only \$20 per ounce for that 95%; but the smelters are selling that same gold at the market price, presumably about \$35 per ounce, and pocketing the difference". Well, we hold no brief for the smelters, they are in the hands of bold bad people, not Sunday-school teachers, of course, but Mr. Kennan is circulating a stupid lie when he makes the above assertion. Indeed, he seems to have such a sacred regard for the truth as to use it sparingly. At the best, he is an ignorant man who is fooling himself and others; at the worst he is a public nuisance.

DISCUSSION

A Matter of Geography

The Editor:

Sir—In your issue of May 8 occurs an interesting article entitled "The Contract System in Mines", by E. Hedburg. The article, however, in locating the Golconda mine at Kingman, suggests some geographic conditions rather difficult to establish, and indicates recent movements of the earth's crust somewhat startling to those familiar with this neighborhood. It can be safely stated that, in 1910 and thenceforth until April 18, 1920 (when the writer last visited the property), the Golconda mine was located some 25 miles northerly from Kingman and about 7 miles from Chloride; and that, if it has changed its position and located itself at Kingman, this event must have taken place within the last 30 days.

The writer craves indulgence in this very mild criticism, since it is only prompted by the complaint of engineers visiting this interesting section, to the effect that many of the mines they come to see are described in various journals as being located "at Kingman"; whereas, in fact, Kingman has no mines at all, being merely the local goods-distributing station on the Santa Fe railway for Oatman, Chloride, and the various mining camps off the main railroad line.

E. VERNON MORGAN.

Kingman, Arizona, May 18.

The Case Oil-Fired Assay-Furnace

The Editor:

Sir—I note the article by F. Borzynski on this subject appearing in your issue of May 15. As I am at the present time operating three furnaces of the type he describes in his article, I wish to comment on same. I differ with him on some of his statements or suggestions regarding the operation of the furnace.

Some time before I had operated these furnaces I had heard statements by some operators who claimed that they could not be worked satisfactorily on cupellation. In my first experience I operated the furnace as does Mr. Borzynski on fusions. In cupellation I could not hold the heat with the door open, and as closing the door is not practical in cupellation I decided to try another system of operating the dampers and front baffle; this system I am now using. I found that the front baffle, with the edge toward the flame, had a tendency to throw the flame upward at about the centre of the muffle and that, when the door of the furnace was open, the muffle cooled down in front and that it was impossible to cupel with the door open. The front baffle being loose I changed it so that the

broad side was toward the burner. The flame then hit the centre of the broad side of the baffle and I found that it gave a very even distribution of the flame around the muffle and the front part of the muffle was nearly as hot as the back. I can now hold the heat in the front part of the muffle, with the door open, very nicely for cupellation. I then set my dampers half-closed and do not move them for either fusion or cupellation. The only time I touch the dampers is in changing muffles. The only parts that I regulate during the time of operation are the oil and air-valves. I have had the very best success on cupellation and fusion in these furnaces.

In reference to Mr. Borzynski's statement on cupellation in cracked muffles, I wish to state that when using cracked muffles with the conditions of operations as above, the flame or gas that may come through the muffle does not interfere. I am also running silver ores that must be feathered during cupellation and I run 33 cupellations in a furnace and feather them perfectly.

In reference to Mr. Borzynski's statements regarding the slot in the door of the furnace and the 'boss', which he calls a "draft-regulator", I find that this 'boss' has nothing whatever to do with the draft regulation on these furnaces. The slot on the furnace-door is something I never use in my operations. I have perfect control of the furnaces with the oil and air-valves for lowering and raising the heat, with the door of the furnaces wide open during cupellation.

Assay of Platinum

The Editor:

Sir—In an article published in your issue of December 20, 1919, Mr. K. C. Laylander makes a statement to the effect that the use of an electric furnace is necessary for consistent results in the determination of platinum by means of the crucible assay. In this connection he writes: "Let the experimenter who doubts this take a known weight of pulverized platinum and introduce it in an ordinary assay charge, and compare his recovered metal with the original amount."

While investigating methods of platinum analysis, in examining the recovery of finely divided or colloidal platinum by fire-assay methods, results were obtained which were distinctly different from those secured by Mr. Laylander. Weighed amounts of platinum were added to regular crucible-charges consisting of silica, litharge, sodium carbonate, borax-glass, charcoal to give a 30-gm. button, and 0.05 gm. of silver chloride. The

platinum was introduced in four ways: the first was to wrap a small piece of platinum in lead foil and add to the charge; the second method intimately mixed finely divided platinum obtained by boiling a solution with formic acid to precipitate the platinum with the charge; in the third, sodium silicate was added to a solution of chloro-platinic acid, hydrogen sulphide added in the cold to form a colloid, and then ammonia added to form a gelatinous precipitate, the mixture being dried and mixed thoroughly with the flux; the fourth method was the same as the third, except that no hydrogen sulphide was introduced.

The fusions were conducted in a gasoline furnace at a temperature of about 1200 C., and in all cases the platinum was recovered without difficulty, as shown below.

Method of preparation	Platinum added Mgm.	Platinum recovered Mgm.
First	0.52	0.51
Second	0.32	0.33
Third	0.50	0.49
Fourth	0.35	0.35

The fact that such reputable assayers as Abbott A. Hanks of San Francisco and W. L. Piers of Denver have obtained similar results, being able to recover known weights of finely divided platinum when added to a regular crucible-assay charge without the use of an electric furnace, would indicate that excessive temperatures are not required for the determination of platinum by means of fire-assay methods.

Engineering Activities of Universities and Government Bureaus

The Editor:

Sir—I have read the report, published in your issue of May 15, by the Mineral Resources section of the Commonwealth Club. Having taken some interest in the plan of the Massachusetts Institute of Technology, I note particularly the brief comment in the report regarding it. Apparently the committee fears that neither the contracting companies nor the Institute itself will find the scheme advantageous. As is pointed out, however, the test of time will be required to answer this point satisfactorily. Apparently co-operation for mutual benefit is the keynote of the plan, in which 200 companies, whose activities require technical consultation, among them the Miami Copper Co., are already participants. In consideration of a substantial annual retainer, the Institute undertakes to give access to its library and files and to arrange for conferences on problems pertaining to the operations of the contracting company; to assist in finding suitable men for doing special research and for filling permanent positions not only from among its undergraduates and alumni but from among specialists and consultants in general; and to advise as to the best means and place for conducting technical investigations and research, either in its own laboratories or elsewhere. The directors emphasize the fact that they make a strictly

business arrangement by which the company pays well for a definite service that is always available. They recognize, doubtless, the psychology that causes us to deprecate what we get for nothing, or conversely, leads us to value the things that cost us something. It would seem that if the professors and instructors of an institution for technical education are to train and fit young men for useful careers, which is their real function, they must come in contact with the actual application of their science to productive industry. Co-operation with the executives of corporations in the solution of practical problems ought to prove helpful. The student will have the incentive of knowing that some, at least, of the tasks at which he works are concerned directly with the business of actual production; and he will be stimulated to do his best by the knowledge that there is a prospect of material reward in the shape of lucrative employment. The same hope of definite future advantage will influence the return of graduates for further research. This is in accord with the universal tendency to lengthen the period of training for technical students. At first thought there may appear reason for antagonism or resentment on the part of the practising consultant because of an apparent poaching upon what he has come to view as his special preserve. However, on more careful consideration, he will find probably that the advantages afforded him more than compensate for any apparent competition in his professional activity. The Division of Industrial Co-operation and Research, established to direct this department, states that it neither wishes nor intends to confine its scope to the personnel or facilities of the Institute, but rather aims to select for its client the best individual or organization for performing any particular investigation. Doubtless a large concern like the Miami company will maintain its regular staff of consultants; but they will have available, besides the thoroughly equipped laboratories of the Institute for special investigations, a convenient and organized source of advice as to where, and from whom, desired information can best be obtained. We presume that the practising engineer himself will have occasion to make use of the library and files of the Institute, which should rapidly increase in value as a result of the present plan. The accurate data on any given subject will accumulate rapidly and will be more complete and comprehensive than could ordinarily be found in the office of a firm of engineers. One of the greatest needs of industry today is to utilize the reservoirs of science already available; this is the purpose of applied research work, and the Technology plan seems to be a step toward efficient and organized research.

San Francisco, May 19.

A. B. PARSONS.

APPROXIMATELY 101,000,000 lb. of copper was sold in the United States in April. This compares with 320,000,000 lb. in March, 89,000,000 in February, and 239,000,000 in January, making a total of approximately 750,000,000 lb. sold since the first of the year. Production in the same period was approximately 550,000,000 pounds.

The Spassky and Athasar Copper Mines in Siberia—II

By J. MACKINTOSH BELL

INTRODUCTION. The copper deposits of Djes Kazgan, identified with the mines of Athasar, are situated in the government of Akmolinsk, in Russian Asia, about 290 miles a little west of south from Athasar village, and some 510 miles from Petropavlovsk on the Trans-Siberian railway. Communication with the mines was formerly maintained over the stage-road from Petropavlovsk through Athasar, but latterly it has been feasible only across the desert of northern Russian Turkistan to the station of Djou Sali on the Orenburg-Tashkent railway about 250 miles south-westerly. The properties of the former Athasar Copperfields, now incorporated with the Spassky Copper Mine, include, in addition to the copper deposits at Djes Kazgan, the coal mine at Bai Kanour, 85 miles to the west, and the settlement of Karsak Pai, where the concentrating plant and smelter are situated.

From a historical standpoint, or, possibly more correctly, pre-historical standpoint, the region surrounding Djes Kazgan is one of extreme interest. Ancient roads along which caravans from India and China to European Russia have traveled from time immemorial pass close to the mines, numerous graves covered with piles of stones and containing bronze implements testifying to a people long since departed. But even more remarkable are the old mine-workings around Djes Kazgan itself, where many open-cuts with galleries ramifying therefrom show that a people skilled in mining worked the deposits so long ago that the workings have had time to become filled with waste and mantled by a slow-growing desert brush. The open-cuts vary in size from shallow pits to huge excavations 750 ft. long, 125 ft. wide, and at least 40 ft. deep. Having regard to the simple instruments that were evidently used in the primitive methods of mining, it is evident that the operations, during which such extensive workings were made, must have extended over a relatively long period of time and that many people were busy. Apparently only oxidized ores were mined, but it is estimated that over a million tons of rock was moved containing probably not less than 10,000 tons of copper! Slag-heaps and occasional pellets of metallic copper close to the mines indicate that smelting operations were conducted, while heaps of rich copper ores adjoining piles of much poorer material near water-holes would seem to imply that the ore was concentrated by water before smelting. The fuel used in smelting was probably either kissick or desert scrub.

Who these ancient miners of south-western Siberia were we have no authentic record. They probably came from the south, as the remains of smelting operations lie along the streams in that direction, and, judging by the few fragments of pottery that have been found with designs of a Persian aspect, it may be assumed that they

were an eastern people. The Kirghiz, who have inhabited the steppes for more than 150 years, have no stories of them; the pits give the impression of being untouched for four or five hundred years. The Russians generally describe the old workers as having been Kalmucks, but as this name is applied to so many different types of people in Central Asia, the designation has no significance.

During the middle of the last century, Oulatau, about 50 miles north of Djes Kazgan, from which the Cossacks were eventually driven by the Kirghiz, was a frontier post held by the former as a base against marauding bands from Bokhara, who swept the steppes to the south. It was evidently while quelling one of these disturbances

BRINGING HAY TO DJES KAZGAN

that the Cossacks found the ancient mines, which they brought to the attention of Oushakoff, a Russian merchant-engineer from Ekaterinburg, who had already established copper mining in the region at Yuspensky, about 260 miles east. Oushakoff obtained concessions from the dominant Kirghiz chief of the region in 1850, but no great headway in the development of the mines seems to have been made until his partner, Ryananoff, who had been associated with him at Yuspensky, sent a party of engineers to the property in 1891. They staked a large area, which was held by special Imperial grants until 1904, when the mines were brought to the attention of English capitalists. In 1907 the Athasar Copperfields, Limited, commenced operations and in 1913 the Spassky Copper Mine, Limited, which was already largely interested in this company, acquired the remainder of the shares.

Development of the Athasar copper mines under English control proceeded rapidly and large quantities of ore were blocked out. To make this available, the coal mine at Bai Kanour had to be opened up, supplies of

scitable limestone and ironstone flux procured, and concentrators, furnaces, and other smelting plant erected. The site for the reduction works was chosen at Karsak Pai, as it is conveniently placed for all the raw materials, and it has, relatively speaking, a good supply of water. A railway was projected to connect both coal and copper mines with the reduction plant.

Probably the greatest difficulty was the transport. All mining supplies had to be brought hundreds of miles across the steppes from Petropavlovsk or over the shorter but more difficult stretch across the desert from Djou Sali. The climate of the region is not one in which these long treks with oxen, horses, or camels were easy. The summer is long, dry, and intensely hot; the winter equally long and cold. Dust-storms rage occasionally in summer, and blizzards of terrific fury in winter. Rain in summer is scant, but occasionally a heavy downpour for a brief spell deluges the arid hillsides, gouging deep channels where runnels only existed before.

Labor has never been an easy problem, the Russians being fewer in number and less efficient than at Spassky or Yuspensky, whereas the Kirghiz are less organized and apparently less tractable.

Notwithstanding these obstacles, work advanced well until the War broke out. A vigorous building program was in progress. The War took men away from the mines, interrupted transportation, raised the cost of supplies, and hindered every endeavor. Meanwhile new capital became necessary, but it was precluded by the Treasury restrictions in England from being available. The company, consequently, had to turn to its current profits, derived from the Spassky, in order to continue operations. The impossibility of obtaining ordinary supplies, such as rails, further embarrassed the management and all sorts of devices had to be adopted by the engineers in charge. Thus, in order to transport the machinery required for the mines and smelter from Djou Sali, a temporary line of railway was built, the supply of rails available being 9 miles long and the train carrying supplies $1\frac{1}{2}$ miles long. When the train had advanced as far as possible, the rails from behind were lifted and used for the next relay. No less than 500,000 tons was transported in this way between the outbreak of the War and the first year of the revolution. Trouble with the Kirghiz delayed the caravan and for two winters it was parked in the snow, but eventually arrived at Karsak Pai with the loss of but a few bits of timber and a number of tarpaulins.

The evil influence of the revolution does not seem to have been felt at Djes Kazgan, Bai Kanour, and Karsak Pai so soon as elsewhere, but in time it worked its way even to these remote settlements, paralyzing the strenuous efforts of the management and in time closing the mines and smelter, before the latter had commenced to produce.

REGIONAL GEOLOGY. The most interesting rocks in the portion of Central Asia under review are a great sedimentary series of Permo-Carboniferous age. Near Bai Kanour these overlie two groups of metamorphic rocks: (1) chlorite schists and schistose porphyrites; (2) slates and cherty quartzites with limey layers.

The exact relationship of these two groups to each other is not clear, but it is thought that certain of the schists of the first group are merely the more metamorphosed equivalents of the definite sedimentaries of the second group, while others are unquestionably highly altered volcanic or other igneous rocks. Other varieties of schist occur, and banded ironstones, resembling those of North America, are found enclosed therein, notably near Karsak Pai. The two groups are cut by granite, often porphyritic, and by porphyries. Serpentine is found that have not been exactly correlated to the other rocks. Quartz veins, in places exceedingly rusty and containing gold and silver, are of widespread distribution within the schist.

Southward, the Permo-Carboniferous sedimentaries and the underlying rocks, which are all more or less disturbed, are overlain by a series of white and red clays with interbedded coherent sandstone. These continue as far as the Aral sea; they are marine Tertiaries.

The Permo-Carboniferous series consists of four more or less distinct groups, measured from the lowest as follows:

1. Conglomerates, sandstones, and arkoses.
2. Chert and limestone.
3. Conglomerates, sandstones, and shales with carbonaceous seams.
4. Sandstones, conglomerates, shales, thinly bedded limestones and cherts.

With the first group are associated important deposits of iron and manganese, about 20 miles north-west of Djes Kazgan; the second contains the thickest and most extensive beds of limestone known in the locality; in the third group coal seams may be expected; in the fourth are the copper deposits of Djes Kazgan.

TOROGRAPHY. In contradistinction to the monotonous stretches of desert extending north-westward from the Orenburg-Tashkent railway, scant in vegetation and unrelieved by any prominent eminence, the country in the immediate vicinity of Djes Kazgan seems distinctly hilly. However, as a matter of fact, the variation in elevation between valley and crest amount at most to only a few hundred feet. The main valleys into which the extensive southern plains merge are broad and open, and the subsidiary valleys ramifying therefrom are shallow and trough-like. The slopes between are generally gently inclined and well graded. In places, however, the harder rocks appear as pronounced ridges or mesa-like buttes.

In early spring when the melting snows provide abundant moisture the generally drab color of the arid hillsides are brightened for a few weeks by brilliant flora, chiefly red and yellow tulips, with pink and yellow lillies. The streams at that season of the year flow unceasingly, but later even the largest in the vicinity of Djes Kazgan become mere chains of waterholes, and the mines have to depend for their supply of water on that derived from the workings, which is unfit for drinking, or upon wells and catchment basins.

DETAILED GEOLOGY. The copper ore is found in the uppermost group of rocks forming the Permo-Carbon-

THE TRAIN CROSSING THE STEPPES

iferous series. This group, 4000 ft. thick, may be subdivided into four members:

1. At the base, 600 ft. of limestone with interbedded sandstone.
2. Over 1750 ft. of gray sandstone, red sandstone, fine conglomerate, and shale. Of this, the lower 630 ft. and upper 335 ft. consist only of sandstone.
3. About 1050 ft. of shaly beds.
4. 600 to 1000 ft. of cherts, with some shale and limestone.

The copper deposits seem to be associated mainly with the sandstone included in No. 2. This contains grains of quartz, feldspar, muscovite, magnetite, and hematite. The cement is variously argillaceous, chalcadonic, or calcareous. The two types of sandstone, namely, the red and the gray, grade into each other by an increase or decrease in the amount of hematite, which seems to be largely original. The sandstone passes into shale both

upward and downward or along the strike and, consequently, forms elongated lenses.

The immediate vicinity of the copper deposits shows a somewhat indefinite dome-shaped uplift, complicated by a couple of minor folds and by numerous normal faults. The strike of the beds is east and west, but there are naturally variations in every direction. The dip is predominantly southerly, at gentle angles, 15° to 30° .

THE COPPER DEPOSITS of Djes Kazgan are tabular in form, their area being great in comparison with their thickness. Probably the term 'sheet', which conveys the idea of considerable lateral extent in contradistinction to thickness, is the most applicable. In form, they bear a considerable similarity to the lead-zinc deposits of Joplin, Missouri.

All told, a great many distinct sheets have been found within an area of about 20 square miles. These occur in seven or eight distinct localities, each showing a number

A TROIKA ON THE STEPPES

of deposits occupying successive beds of sandstone, separated by beds of shale, in the sandstone-shale member of the Upper Permian-Carboniferous, and invariably associated with faults. Four great ore-horizons have so far been disclosed.

The larger orebodies so far developed at Djes Kazgan contain from 30,000 to 50,000 tons of ore. One particular orebody, known as the Annensky, covers an area of 200 by 500 ft. Another, known as the Petro Hill, is 350 ft. long and 250 ft. wide. The 'A' shaft orebody is 250 ft. long by 450 ft. wide. The thickness of most of the ore varies from a foot and a half to five feet, although local thicknesses of 27 ft. are not uncommon.

The orebodies cease by 'pinching out' either gradually or bluntly against an older fault or joint. The wedging out of the orebodies may be due to a decrease in the amount of fracturing or a change in the granularity of the enclosing sandstone, or to the exhaustion of the ore-bearing solutions.

The known orebodies are situated for the most part either on the crests of hills or on the slopes. In the valleys, which are generally underlain by shale, the ore-bearing sandstones do not generally appear, though naturally they may be expected beneath, and a number of deposits have been located by boring.

The rock most favorable to ore deposition is a highly-jointed medium-grained gray sandstone, containing quartz and feldspar granules in a calcareous matrix. The copper-bearing minerals seem to have replaced first the calcareous matrix, then the feldspar, and lastly the quartz. The orebodies often cross the stratification of the sandstone, the richer ore grading through slightly impregnated material into barren sandstone; usually they lie below an impervious shale, but there are instances where they cease upward in sandstone below shale.

The deposits have a close relationship to faults or sharp anteformal folds that antedate ore precipitation. Faulting has occurred since, but the later displacement of the orebodies seems to have been unimportant. The outcrops of all the deposits are invariably oxidized, the depth of oxidation depending on such factors as the inclination of the deposits and the position of the water-level, which now stands at from 7 to 30 ft. in the valleys and from 40 to 50 ft. on the hill-crests, but is greatly complicated now, as probably in the past, by the occurrence of numerous highly porous beds interstratified with impervious beds. The copper-bearing minerals of the original ore consist chiefly of chalcocite, bornite, and pyrite. The gangue-minerals are calcite, quartz (both crystalline and jaspery), barite, siderite, aragonite, and dolomite. The secondary ores include bornite, chalcocite, native copper, cuprite, malachite, azurite, chrysocolla, cerussite, and native silver, with calcite, aragonite, quartz, chalcodony, siderite, gypsum, limonite, hematite, and manganese dioxide.

The chief mineral of the oxidized ore is malachite. The oxidized ores of most of the outcropping sheets do not extend ordinarily more than 30 or 60 ft. from the surface, but they go much deeper where the orebodies occur near

important faults. In some of them a considerable portion of the copper has been leached, while rich parts of the sulphide orebodies, containing chalcocite and secondary bornite, indicate that there has been in places in the inclined deposits a certain amount of secondary enrichment through the downward migration of copper leached from above. The change effected by secondary enrichment in horizontal sheets has been rather of mineralogic composition (that is, the local alteration of chalcocite to bornite or of bornite to chalcocite) than of an addition in metallic content.

The ores of Djes Kazgan, both sulphide and oxidized, are highly silicious. The oxidized ore is essentially a sandstone, more or less completely replaced by malachite. It is ordinarily soft and consequently easily mined. It is generally lower in grade than the sulphide ore, although some of it is higher in grade and contains from 14 to 17% copper.

The sulphide ores, divisible into rich smelting ore and disseminated or milling ore, which occurs on the edges of the ore-sheets, are both hard sandstones unequally replaced by copper minerals. The smelting ore ordinarily runs from 11 to 16%; the milling ore from 4 to 7%. The sulphide ores contain appreciable quantities of silver, generally from 6 to 8 oz. per ton in the richer grades.

The depth to which the ore persists is not yet known. Development by shafts and drifts has so far not extended to any great distance below the surface, not more than 200 or 300 ft., exploration having been chiefly by boreholes which have cut orebodies down to a depth of 700 ft. As the ore-bearing sandstones extend to great depth it is probable that orebodies as yet unknown will be discovered by aid of further exploration.

GENESIS OF THE ORE. The deposits of Djes Kazgan were formed, in the first instance, by ascending solutions, and later were changed in mineral composition by descending solutions, with some attendant shifting of the copper content.

There are many evidences that the original ore was not of sedimentary origin and was formed by ascending rather than descending solutions. Were it sedimentary, the ore would not cross the bedding-planes as is frequently the case; it would not necessarily be confined mainly to the vicinity of faults, and it is improbable that recurring conditions would be favorable for the deposition of ore in a number of horizons.

That the solutions were ascending, seems to be shown by the nature of the original sulphide minerals, containing appreciable quantities of silver and traces of gold associated with quartz and barite; the occurrence of the ore in close proximity to faults, which are always mineralized and commonly below impervious roofs of shale; the connection of the chief centres of ore deposition with anteformal folds rather than synclinal; and the tendency of the orebodies to be superimposed one upon the other.

No evidence is available as to the original source of the copper. The metal may have been widely disseminated in the sedimentary rocks and been leached therefrom by

meteoric waters to rise subsequently under artesian conditions. It is possible that the deposits may be of magmatic origin, but if this were the case it is remarkable that no igneous rocks later than the strata in which the orebodies occur are visible near Djes Kazgan. At Yuspensky, 260 miles east, rich copper deposits occurring in lensoid lodes occupy a faulted zone partly in what are thought to be the oldest division of the Permian Carboniferous, and partly in porphyries and porphyrites. While the majority of the latter antedates the beds with which the deposits are associated, there is a possibility that certain of them may be younger.

METHODS OF MINING. Shafts, sufficiently large and adequately equipped to handle the ore, have been sunk at most of the principal groups of deposits, and drifts extended therefrom to the limits of the orebodies, cross-

easily accessible manganese etc which received favorable mention from the American geologists who toured the island in the spring of 1917. Early in 1918 a company formed secured control of these deposits and undertook the exploitation of the property. However, the sudden cessation of the War interrupted plans, and little ore has been mined since.

Scheelite is much more abundant in New Zealand than wolfram, being widely distributed throughout Otago and Marlborough, where it occurs in quartz lodes traversing mica-schist country. These lodes are always more or less auriferous, and some of them were worked for their gold content years before the fact that they contained scheelite was known. The mineral is also found in gravels derived from the denudation of the lode-

IDEALIZED SECTION OF TYPICAL ATBASAR DEPOSIT

LARGE SCALE DETAIL

drifts, inclined winzes and raises being advanced for purposes of further development. At the end of 1915, 543,900 tons of ore averaging 10.7% of copper, including 154,818 tons of 13.1% ore, was ready for stoping, the greater proportion being sulphide ore.

As already indicated, it is planned to assemble at Karsak Pai the coal from Bai Kanour, the ore from Djes Kazgan, and the fluxes from a variety of localities. Since the site was chosen in 1912, a small town has grown up there with numerous buildings for offices, staff, and workmen, and with a plant for treatment. It was not proposed in the first instance to treat the oxidized ore. The sulphide ore was to be concentrated by water and the concentrate smelted in reverberatory furnaces. The plant, which is practically complete and would long ago have been active but for the War and the ensuing events in Russia, is designed to have an annual capacity of 5000 tons of copper.

NEAR the town of Ponce, situated 25 miles west of Cardenas, Cuba, lie extensive deposits of high-grade and

bearing areas. At the present time the largest amount of scheelite is obtained from the neighborhood of Glenorchy, at the northern end of Lake Wakatipu. Here the ore is found in rich bunches irregularly distributed in rather narrow quartz veins. The quartz throughout contains a little scheelite and a very small quantity of gold. For the reasons that the scheelite is relatively friable, and that slimed scheelite is difficult to save, the ore is reduced to powder in several stages, being treated by jigs between these operations. No attempt is made to save the gold. At Deep Creek, in Marlborough, the scheelite is much more sparingly disseminated throughout the ore, which, moreover, contains a notable amount of gold. The only lode worked is large and irregular. Here the ore is pulverized in one operation in a stamp-battery, the gold being saved on copper-amalgamating plates and the scheelite on Wilfley tables.

THE diamond production of the Union of South Africa for 1919 was 2,588,017 carats valued at more than fifty-seven million dollars.

Mr. Govett on the Gold Problem

Herewith we publish part of the speech delivered in London by Francis A. Govett, chairman of the Ivanhoe Gold Corporation, a famous West Australian mining enterprise, on the occasion of the annual meeting of that company.¹

The problem of the premium on gold and the exchanges generally is not at all well understood; it is questionable if anyone really is master of the subject, and it seems to me we are all groping in a sort of fog, when you see what is done by expert financiers, as, for instance, by the Indian government in their futile attempt to stabilize the Indian exchange. With the other gropers I am going to turn my humble lantern on the fog and offer you a few suggestions. First, let me call your attention to the fact that, in this free-trade country, the gold-producers have not been free to trade. All through the War until quite recently, we have been compelled to sell our output to the Government at the mint-value of our gold, while the silver-producers have rioted in possession of the open market, subject only to the excess-profit duty for such as could not entirely escape. This is the grossest favoritism and neither just nor honest. The Government just stole the whole of our profit and let the silver-producers go free and profit by the preposterous rise in price, which there is good reason to believe would never have taken place but for the arbitrary interference of the Indian government in its embargo on silver exports from India. However, I only mention that in passing. The gold premium in any country is, of course, roughly the equivalent of the highest measure of adverse exchange against that country. Gold represents the parity of exchange, and the more adverse it is the higher the premium which must be paid for gold. It seems to me that gold is fearfully regarded as a sort of fetish, while it ought to be just a useful servant. In normal times it is a most useful, efficient servant. In times like these I submit that it would be vastly more useful than it is if it were not held back, but freely used for what is, after all, its primary function—the protection of the foreign exchanges.

Leaving out the complication that gold itself is a commodity, it has two main functions, which in normal times apparently do not conflict, but which in times like these are irreconcilable. Gold men seem to have no doubt that the chief function of gold must be to back the internal paper currency in any country; that is to say, that you must keep sufficient gold in your vaults to meet any possible panic run, to exchange that paper into gold. I have never heard of but one suggestion of a cent, per cent, reserve in gold; that was for a special reason, and universally the gold in reserve is insufficient to redeem more than a very moderate percentage of the paper issued and in circulation. A moment's reflection will show you that in practice this means that the notes issued

are only really backed by gold so long as gold is not seriously demanded; for in times of panic or serious danger either the Bank Act is suspended or the convertibility at once suspended. That is to say, the gold backing for the paper currency is entirely Christian Science; you can get gold for your paper only so long as you do not want it. Let us draw a logical deduction from that. For six years past, except nominally, the convertibility has been suspended, and, except in very small amounts, you could not get gold for notes; but the credit of the note—the currency, either Bradbury or Bank of England—has not been damaged to the extent of a penny piece. The fact that prices have risen does not mean depreciation of the currency; nor is currency inflated; currency is not inflated until the currency in circulation is in excess of the demand. At the present time more people with higher wages have been competing for scarcer commodities, more currency has been required, and paper internally has not depreciated in gold. Try it for yourselves. You can get probably fifty or a hundred sovereigns from the Bank, once at any rate, without being followed by a detective; go and see if you can buy more commodities with your hundred golden sovereigns than you can with a hundred Bradburys. You cannot do it, unless you sell your gold to an illicit buyer who proposes to melt it down. I regard that as Q.E.D. The deduction is that the notes issued must, and do always, in fact, rest on national credit, and not on gold, and this function of gold in practice is just a fetish.

The second function of gold is vastly more important. As an almost universal measuring rod of the value of commodities gold is useful; in fact, indispensable, and all nations ought to have their currencies based on gold. There is nothing else to take its place. The exchange position between two countries is just the measure, in gold, of the balance of indebtedness on either side for commodities bought and sold; that is the balance of trade. Ultimately, of course, the imports of our country must be paid for by exports if equilibrium is to be maintained. Temporarily this balance can be adjusted and the exchange protected by export of gold, but ultimately it must be settled in commodities or other services known as invisible exports. When exports are continuously insufficient to balance imports a nation is getting into debt. This fact is shown by a fall in the exchange, for differences are paid by bills of exchange, and as they get scarce a larger amount of currency in one country must be paid to obtain bills of exchange in the other. The exchange falls—that is, the price of bills rises—until the gold point is reached, when it becomes cheaper to export gold than to buy bills. At this juncture the directors of the Bank, who hate parting with their imaginary gold backing for their note-issues, start in to interfere with this function of gold, which is to

protect the exchanges. They proceed to raise the bank-rate, regardless of the losses involved thereby to the whole of the trading community in having to pay a higher rate for loans where there is no increased demand for loans, their object being to attract foreign money here to benefit by the higher rate, and so obviate the need of exporting gold. To me this seems a singularly cumbersome and costly method, callously shoving the cost and consequent loss onto the backs of entirely innocent parties. It also tends to obscure the real position of the amount of the international indebtedness; in a way it is faking the hand of the pressure-gauge, the exchange. This, however, in normal times perhaps is not of much importance, though what it costs in dearer money, which is of vast importance to the traders, is just hidden.

So much for normal conditions; now declare war. First step, embargo on the export of gold. Here, then, you arrive at the ridiculous position that in time of serious need within the country the gold in the vaults is no longer available to back the internal note currency, lest it be wanted to protect our foreign exchange, and when it is needed to protect the foreign exchange it is not allowed to be used for that purpose by an embargo on export for fear of there being no longer a gold backing for the notes, which is absurd. With the outbreak of war our imports from America, of course, at once enormously increased, and, in order not to part with gold, the exchange was 'pegged' in other ways, namely, by borrowing in America, which was costly, and by shipping to America every block of interest-bearing American securities on which the Government could lay its hands, which was also very costly, instead of shipping non-interest-bearing gold. Now, you will note that gold itself has no commercial value outside its value as an ornamental commodity, which is comparatively inconsiderable, outside India and China, which have always regarded metals as the basis of wealth, or wealth itself. Beyond the needs of gold countries for actual coinage and later as a conventional backing for note-issues, no country seems willing to absorb more than a given amount of gold, as it is a costly business, for it bears no interest: it is just dumped into a vault to be held there as the limitation of, and the backing of, the paper currency, for which purpose, as I have said, it is never used when need is really great. There must then come a point when, so far from wanting to absorb more gold, a country will and must rebel against taking more, and at that point, if this function of gold be freely exercised, the exchange will steady. This point did arise with Norway. I always said that the proper course was not to hoard our gold as an imaginary backing for our note-issues, but to force it upon reluctant America, and it is rather curious that on the first threat in March to pay off a hundred millions in gold the American exchange rebounded some 70 cents. Was it *propter hoc* or *post hoc*? I do not know, but it is suggestive. Whether that be the case, this at least is plain: when exchange falls to the gold point, and we won't ship gold, exchange must further fall, as it did fall when the artificial pegs were taken out.

The result is that first, we are still paying about 30% higher for everything which we buy from America; we were already heavily in debt, which we could not pay, so that this implies increasing that debt much faster than is necessary, while an exceedingly bad point is that it obscures the real position. There are few people, even business men, who think much about exchange. They just accept the fluctuations as something which cannot be remedied, and are satisfied to leave the matter in what they regard as expert hands. The general public knows nothing about exchange. The result is that the writing on the wall, the indications of the gauge, are absolutely disregarded; if you face the facts, the country is bankrupt, if bankrupt means that you cannot pay, that you can only buy on credit on ruinous terms, and the debt is rolling up. Even now we are not exporting enough to balance our imports, even including the increased exports, and the colossal freights which still are charged by British shipping, yet the heedless public continues to spend its money in an orgy of extravagance, increasing the adverse balance of trade by buying American motor-cars and tires, and a host of unnecessary things which are quite as well supplied from here.

So much for gold; but to point the moral of this sermon it is necessary to add a few short notes on silver. Passing by the extraordinary favoritism which has been shown to silver-producers, the troubles of exchange are plainly bad enough between countries with gold currency, but it is made far worse by the fact that two big countries, India and China, in practice are on a silver basis, with smaller suffering communities like Ceylon or East Africa. To be as short as possible, about twenty years ago, when silver was low and the rupee had fallen to about 14 pence, the Indian government embraced the bi-metallic heresy, with fine contempt for the economic law that "it is not possible to fix a ratio between two fluctuating values". They fixed, as they thought, to all eternity, the rupee at 1s.4d., or 15 to the pound. Curiously enough, though thoroughly unsound, it was good business. For many years it looked as if they were right and as if they had fixed the rupee for a reason not immediately apparent. In fact, the value of the silver in the rupee never rose above that figure until the War, and consequently the rupee was practically a token coin. When at last silver rose, the dog began to bite the pig and the law began to work. Of course, the ratio was blown to smithereens, and the rupee rose to 2s.4d., above which figure all costs in India paid from here had risen 75%, which was disastrous. Then the Indian Council, with a committee of experts, and the Secretary of State arose and proceeded to reaffirm the bi-metallic heresy, this time proclaiming they will have stabilized the exchange, by fixing the rupee at 2s. instead of 1s.4d. when once gold gets back to parity. They thought that it would be better stabilized by tying the rupee to gold and fixing the silver in the rupee at 2s. or 10% of the gold in the sovereign, instead of tying it to the pound, and that the rupee would rise and fall with gold instead of with the currency which they call sterling. But as the rise in gold is the exact measure of the so-called fall in cur-

rency, the change, of course, is no change at all. It seems to me the rise in the rupee must be just the same, whether in the direct ratio with the rise in gold, or, conversely, with the fall in currency or sterling. Their idea seems to be that when gold gets back to parity, even though the value of the silver in the rupee falls below 2s., the rupee would become a token coin.

Some of the immediate results of the enactment are that the exchange was not stabilized at all; the rupee immediately rose from whips at 2s.4d. to scorpions at 2s. 10d., at which price I honored a bill which I propose to frame as a monument to their sagacity, since when it has fallen back to 2s.4d. the fluctuations not following at all the price of gold as they said it would, nor indeed the fluctuations in silver. But will the rupee be fixed at 2s. when at last it gets there? Will it consent to be a token coin? This is the point. I spare you that, but the fact remains that we have not been yet relieved in any way by this magnificent enactment, for we were exposed to the additional loss involved by the further rise from 2s.4d. to 2s.10d., while if silver should fall again to a normal price, we shall be deprived of any benefit under 2s.; in other words, their deliberate intention was that we were to have our working cost increased by 50% in perpetuity. And they plumed themselves "on the skill, courage, and resource which the government of India and the India Office have shown in dealing with the complicated and ever-changing problems that had presented themselves in connection with the India currency system", which is rather queer reading when the minority report attributes the whole of the trouble to the constant interference of the Indian government with the exchange and with free dealing in gold and silver. As I have said, there is indeed strong reason to believe that had it not been for the embargo on export of silver from India the great rise in silver would never have taken place.

Now for my conclusions. Gold has rendered good services; it has provided a most convenient common measure for the internal exchange of all commodities, and for international exchange, there being a fixed amount of fine gold in the unit coin of any country. This being so convenient, it is absurd that complications involved by the use of silver as a collateral basis of exchange should be tolerated, or that any country should remain on a silver basis; still more absurd that any of these countries should be a country within the British Empire, like India, Ceylon, and East Africa. We cannot compel China to come in, but there should be a uniform currency for the Empire with its base the British sovereign. It does not matter what may be the denominations of the subsidiary token coins so long as they are really tokens and not like the rupee, a coin of value above 2s. and possibly a token when silver falls below. Internally the use of gold itself as pocket coinage is most extravagant; for six years past we have done well without it, and I have shown that in practice it is never used in times of need for one of the purposes for which it nominally is available—the backing of the note issues

in circulation. To me it seems, then, better to recognize the actual facts that the note issues are not backed by gold at all but rest on national credit; to confine the use of gold to the sole function of the adjustment of international indebtedness and actually to use it when it is wanted; that is to say, instead of hoarding the useless gold in the bank vaults it should be used in paying our external debts at \$4.86 instead of our buying bills, as we have done, as low as \$3.20 at a heavy loss, which means that we were paying 40 to 50% more for what we buy and increasing our indebtedness by that amount. Take the whole of the gold and hurl it at them; one of two things will happen—either the exchange will immediately rise in their unwillingness to take gold, or they will take it and we shall have saved some further debts, and then we shall be no worse off than at the present moment and at least we then shall know where we stand, for we shall be back on the real basis of our national credit when, perhaps, at last we may begin to grasp the facts and to economize a little, while the internal credit of the Bradbury will still be unimpaired.

A SHAFT 12 miles deep is proposed by Sir Charles Parsons, lecturing recently at the Royal Institution. He says that the cost of boring the hole would not be so very great. In countries where the atmosphere is dry the sides of mine shafts are cooled by sprinkling them with water, the evaporation of which cools the rock. This effect might be augmented by artificially drying and cooling the air before passing it down the mine. With still greater depths of shaft further methods of cooling would probably be necessary. The heat might be carried upward by means of brine circulated in a closed ring of steel pipes with a rising and descending column, or a simpler method would be to arrange for a rain of liquid air down the shaft. When sinking the deeper portions of the shaft probably shields would be required to protect the miners from the splintering of the rock, since the intense compressive stress splits off scales from the surface, sometimes with considerable violence. When he first brought forward his suggestion, in 1904, the estimate of the time required to sink a shaft twelve miles deep was eighty years; but with improved machinery and methods the records have been so much lowered that he now thinks an estimate of thirty years reasonable.

THE aluminum produced in the United States during 1919, was valued at \$38,558,000, as compared with \$41,159,000 in 1918. This decrease of \$2,601,000 was probably due to a curtailment of production in 1919, forced by the accumulation of large stocks of aluminum by both the Government and the manufacturers in 1918. The market prices quoted during the first four months of the year were lower than those which prevailed during the remaining months, and apparently most if not all of the stocks were taken by the beginning of the last quarter.

TWO THOUSAND men are engaged in the oil industry of Pechelbronn, Alsace, where 50,000 tons of petroleum products are produced annually.

Froth-Flotation at Broken Hill

By C. C. FREEMAN

*INTRODUCTION. Although great progress has been made in flotation of the Broken Hill silver-lead-zinc ores, no paper dealing with this subject has been presented to the members of the Institute since James Hebbard's valuable contribution in 1913.

Almost every discovery or development in the history of flotation has formed the basis of a patent, and but few experimentalists have overlooked the fact that their investigations might lead to the establishment of a patentable process. This, together with the aftermath of patent litigation, naturally resulted in secrecy being maintained in matters appertaining to the art, and the industry as a whole has consequently suffered considerably. Much valuable time has been wasted through numbers of men repeating work along certain lines, which, unknown to them, had already been thoroughly exhausted by others, whereas a lot of this would have been avoided by a freer interchange of information among those directly concerned.

Owing to differences in the ore treated and the various applications of flotation concentration in relation to gravity methods, the flotation problems of the various mines differ considerably. This, together with the secrecy previously referred to, has resulted in the development of numerous systems and machines, most of which would appear, to the casual observer, to comprise separate and distinct processes. I have endeavored to show how much these processes have in common with one another, and, at the same time, have tried to convey some general ideas on flotation to those members of the Institute who are not directly associated with this branch of concentration.

Many theories have been expounded dealing with the underlying principles that control flotation, and while some of these appear to explain satisfactorily certain of the phenomena, a number of them are of little practical use, and are really only of academic interest. Generally speaking, the men who are directly connected with flotation operations are busily engaged attending to the practical and economic considerations, and have but little time to devote to the purely theoretical aspect, which perforce has to be left to the scientist.

Today all operators have certain general ideas on flotation, but few would dare to predict the result of treatment of an ore by any flotation method without first having recourse to a laboratory or other testing-machine. Undoubtedly, the experimental machine is still the mainstay of the flotation man for all research, investigation, and plant-control work.

Although several of the earlier flotation methods employed other principles, almost all the processes in use in

Broken Hill today rely on the carrying power of air or gas bubbles to which the floated material becomes attached, and this paper will only deal with this type of flotation, which is commonly called froth-flotation.

Developments in flotation have shown that most of the minerals possess surface properties which allow them to become attached to the air or gas bubbles more or less readily. These properties are not, as was originally believed, confined to those minerals having the metallic-like surface of the sulphide minerals, but are also possessed, in some degree, by most other minerals and many artificially prepared salts.

The art of flotation depends on making use of the varying degrees of these properties possessed by different minerals, and, in cases where a separation is required of two minerals possessing the properties to approximately the same extent, by physically or chemically altering these surface properties of one of the minerals, so that one mineral will float more readily than the other.

It may be as well to point out, at this stage, that the terms 'preferential', 'selective', and 'differential' have been used to describe flotation methods whereby one sulphide mineral is separated from another. In Broken Hill these terms are practically synonymous, but, for convenience, I have used 'preferential' when referring to methods based on chemical alteration of the surfaces of one or more of the sulphide minerals, and 'differential' for all other methods where no definite chemical alteration can be detected. It will be noted that the only difference is that in the former case a preliminary treatment alters the physical conditions of the surface of some of the minerals by bringing about a surficial chemical alteration of the mineral itself, and that the actual flotation separation then becomes identical with the 'differential' systems. As will be shown, the general principles involved in the differential methods are the same as those in the older methods that separated the sulphide minerals from gangue minerals, producing what is known as a 'collective' or 'mixed' float. Certain conditions are necessary to bring about the attachment of sufficient air to an ore-particle to cause the latter to rise to the surface of the liquor. In the case of those minerals—such as some of the sulphides—which most readily become attached to the bubbles, flotation will result when the conditions are developed to only a slight extent, but these conditions must be intensified considerably to bring about the attachment of the air and a less readily floated mineral particle. By controlling the degree of intensification of conditions that bring about this attachment it is possible to separate a mineral which becomes readily attached to the bubbles from another mineral, the surfaces of which have a lower affinity for the same bubbles.

*A paper read before the Broken Hill branch of the Australasian Institute of Mining and Metallurgy.

Thus, if a mixture of evenly-sized particles of three minerals— (a) , (b) , and (c) —be subjected to flotation, and if, under the general conditions used, (a) possesses surface properties such that the air-bubbles become more readily attached to it than to (b) , and (b) possesses such properties more than (c) , it will be possible to arrive at a set of flotation conditions whereby (a) can be floated away from (b) and (c) . By intensifying these conditions a point will be arrived at when (b) can be floated away from (c) . If these latter conditions are used on the original mixture the float would contain both (a) and (b) . Thus, the general principles governing the differential flotation and the older collective methods are identical; but, while in the latter case the margin in surface properties in regard to bubble attachment between the least floatable sulphide minerals and the dull, oxidized, or gangue minerals is very marked, this difference is often small in the former case. In collective flotation, therefore, one may vary the flotation-intensifying conditions considerably without materially affecting the result, whereas preferential flotation is a much more delicate operation, requiring careful control in most cases. In view of the fact that the early work in flotation at Broken Hill was directed toward the recovery of blende from mill-tailing, de-leaded by gravity-concentration methods, and also that the blende required more intense flotation conditions than the other associated sulphide minerals, it was only natural that the conditions developed at that time were sufficiently intense to promote collective flotation.

Flotation ideas thus developed along lines that embraced the liberal use of several of the intensifiers, such as power, heat, acid, and frothing-agents. From this it became accepted, at that time, that flotation concentration could only be employed to separate minerals with a metallic-like surface (such as the sulphides) from materials with dull and easily-wetted surfaces. No doubt the fact that so much work was done on more or less weathered dump-tailing, in which the relatively low galena content had become sufficiently superficially oxidized to reduce its flotation properties to at least as low as that of the blende, was responsible for the number of years which elapsed between the establishment of the collective and the preferential flotation methods.

DIFFERENTIAL FLOTATION. As previously stated, the principles involved are identical with those used in the earlier collective-flotation methods, and differential results depend on the control and modification of those principles. The method depends primarily on the fact that, owing to the physical properties of the surfaces of minerals, the bubbles become more readily attached to the surface of some minerals than others, and, by regulating the intensity of the conditions bringing about this attachment, it is possible to form bubbles carrying only the former minerals. The galena in freshly mined Broken Hill ore possesses the floatative property to a greater extent than the blende, and all the differential-flotation methods now used on this field recover the galena in the first float.

Much has been written in technical journals dealing with what may be termed the elements which produce the conditions necessary for the attachment of the mineral particles and the bubbles. A brief review of these may be of interest. The intensity of the flotation conditions produced is the sum of the effect of each of these elements, and those most commonly used are:

1. Air (or gas as CO_2 generated from carbonates in the pulp). This is essential in froth-flotation as a buoyant to carry the mineral. Within limits, the intensity will vary with the quantity of air introduced into the pulp.

2. Agitation. A certain amount of agitation appears to be essential to all flotation. It has been stated that the main function of agitation is to bring about an intimate admixture and distribution of the oil, and, while this is no doubt true to a certain extent, the fact that agitation is necessary when soluble frothing-agents are used would indicate that the function of agitation is not limited to the above. Agitation also plays an important part in cleansing the surfaces of the mineral particles, breaking up the air into minute bubbles, and promoting a coalescence between the oiled particles. The agitation need not necessarily be applied in the flotation machine, and, in some cases, the flow of the pulp through grinding machines, launders, and elevators, after the addition of some or all of the flotation reagents, will provide sufficient agitation for the removal of a readily-floated mineral. Owing to the large expenditure of power for agitation, this subject has received a lot of attention, which has resulted in the development of a great variety of flotation machines. The author's experience, however, has been that, with a given set of conditions, a definite expenditure of horse-power is required to produce a given result, and that frequently a saving in power can be economically effected by increasing some of the other intensifiers or elements.

3. Frothing-agents, which consist of soluble salts, or, more frequently, oils. The American writers have classified oils as 'frothers' and 'collectors'—the former containing more or less constituents which are soluble in the flotation circuit, and the latter insoluble oils which coat the sulphide-mineral particles. A number of oils, particularly many of the Australian eucalyptus-oils, possess the properties of both frothers and collectors. In flotation practice in America great stress seems to be laid on the oil or mixture of oils used; but, while many different oils have been tried in Broken Hill, the eucalyptus and a few coal-tar products are the oils most generally used. American pine-oil or pine-tar oil is used to a limited extent in a few cases. The eucalyptus-oils used consist mainly of dextrapinene and phellandrene. Some of the oils characterized by being relatively low in phellandrene will, in many cases, give good results, but may require the addition of a certain amount of a 'collecting' oil to make the float sufficiently stable. Usually a number of oils or oil-mixtures can be found that will produce identical results, and the final choice in the oil is decided by the cost factor.

4. Acid is a potent intensifier. It is universally used in Broken Hill in connection with blende flotation, excepting in cases where the ore is so calcitic that the consumption of acid becomes prohibitive.

5. Temperature invariably increases the intensity of the flotation conditions. Owing to the high price of fuel in Broken Hill, heating-plant circuits are somewhat expensive, and every endeavor is made to carry out operations at atmospheric temperature. Generally speaking, the end-point of a flotation separation is sharper and more clearly defined in hot than in cold circuits.

Within limits, similar results can usually be obtained by increasing one element and correspondingly decreasing another, so as to retain the same intensification of conditions. Thus, two plants working on similar material may obtain similar results, although in one case very little reagent and a lot of power are used, whereas in the other less power but more intensifying reagents are employed.

Given two minerals with an appreciable difference in their flotative properties, a separation can be effected in a fresh-water circuit by applying some or all of the above elements, and, although this can be applied to the separation of galena from blende in many of the freshly-mined Broken Hill ores, the difference in the flotative properties of these minerals is often so small that such a process is rather too delicate and sensitive for ordinary purposes. Lyster discovered that the presence of salts, such as the sulphates of many of the metals in the circuit-water, retarded the flotation of the blende, and this principle has, either directly or indirectly, been applied in all the Broken Hill mills that are practising differential flotation. When using this system for differential galena-flotation, the blende is subsequently floated from the gangue by increasing the intensity of the flotation conditions by application of acid, heat, oil, or other intensifier. Some of the mines supply the necessary salts to their mill-circuits by using the underground mine-water, whereas those plants using H_2SO_4 in connection with their flotation operations create an ample supply of salts for differential-flotation purposes. The return circuit-water, besides containing these salts, also retains a certain amount of the soluble frothing constituents of the oils used. These conditions are favorable for differential galena-flotation, and advantage was taken of this by the Junction North Company (in their cascading plant), the Central Mine, and the Zinc Corporation (in their zinc concentrator). Very small additions of oil frequently improve galena flotation without raising the blende under these conditions. Prior to the development of differential flotation it was recognized that if the percentage of these salts in the circuit-liquor became too high, blende flotation was difficult, even in hot, faintly-acid solutions. Thus, T. J. Hoover, in 'Concentrating Ores by Flotation', referred to the fact that at the Zinc Corporation plant the blende flotation invariably went off when the quantity of salts in the solution exceeded 3000 grains per gallon.

Reference may be made to the fact that the ore from the Broken Hill lode may be divided into two distinct

classes, consisting of sulphide minerals (chiefly galena and blende) in a rhodonitic gangue on the one hand, and sulphide minerals associated with a gangue containing up to 10 or 12% of calcite on the other hand. The difference in the flotative properties of the galena and blende is slightly less pronounced in the rhodonitic than in the calcitic class of ore, so that differential flotation is somewhat more easily conducted when dealing with the latter ore; but in this case several of the methods which depend on the use of acids cannot be so economically applied, on account of the high acid-consumption involved.

The circuits necessary for the above type of differential flotation are so cheaply obtained that this method is used whenever possible. In some cases, however, the flotation properties of the galena and blende are so nearly alike that the presence of the salts in the circuit solutions will not sufficiently retard the blende to allow of satisfactory differential results. This occurs with some of the rhodonitic classes of ore, even when freshly mined, and in most of the tailing and slime that has been exposed to weathering. The Bradford SO_2 method is largely used for differential treatment in such cases. The presence of SO_2 in the solutions retards blende flotation to a greater extent than the salts referred to above, and this allows the use of conditions sufficiently intense to float even slightly tarnished galena particles without raising the blende. Subsequent flotation of the blende may be effected by removal of the liquor containing the SO_2 , by removal of the SO_2 by aeration or heat, by decomposition of the SO_2 by chemical means, or by further intensification of the flotation conditions by acid and heat. A diversity of opinion exists as to whether it is essential to have salts in solution to obtain the best results with this process. As acid is used in all Broken Hill plants using the SO_2 process, this is of little account under normal plant-conditions, but is mentioned for the benefit of those engaged in laboratory work.

A new method was recently patented by T. H. Palmer, H. V. Seale, and R. D. Nevett, by which results similar to those yielded by the Bradford SO_2 process are obtained. The patentees claim to make a solution of S by boiling tar or other oils in a weak solution of H_2SO_4 in the presence of an excess of powdered sulphur. Whether the sulphur goes into solution as an organic compound, or whether the sulphur removes the fractions of the oil that promote blende flotation, leaving a solution of only the fraction or fractions suitable for galena flotation, is not yet known. Whatever the action may be, the results obtained by the use of this process at the Junction North mine, where the process has displaced the SO_2 process, clearly demonstrate that the process yields the results claimed, and, in view of the fact that subsequent blende flotation can be obtained by heating the pulp only to about 120° F., the process, where applicable, appears to be less costly to operate than the SO_2 process. When operating this process it is necessary to have soluble salts, such as the sulphates of some of the metals, in the circuit-water.

The methods outlined above cover most of the differen-

and flotation at present in use in Broken Hill. Many other processes have from time to time been patented, but very few have actually been tried on a working scale. The permanganate method of T. M. Owen and H. V. Seal is claimed to give exceptionally good differential-galena results on weathered slime, but, owing to the prohibitive price of this salt during recent years, the process has not been applied commercially. This process appears to embrace some of the anomalies so frequently encountered in flotation, in that, whereas the Bradford process applies SO_2 or other reducing agents, and Lyster uses a circuit containing soluble sulphates, etc., and bichromate has been claimed as producing differential-blende flotation, the permanganate (which is an oxidizer) yields a galena float, and the success of the process depends upon using a circuit containing a relatively small quantity of salts in solution. A soda-ash circuit will give sharp and clean differential-galena results on freshly-mined ore, when only little or no oil is used, and has the advantage that the subsequent flotation of even the coarser blende can be very readily obtained by the use of oil and a salt, such as CuSO_4 . This process has been successfully applied elsewhere, and would be particularly useful in districts where sulphuric acid is difficult to procure.

The size of the mineral particles has an important bearing on results, and the larger the particles to be floated the more intense must the conditions be. It therefore follows that, given conditions wherein galena particles have greater floatative properties than blende particles of a similar size—or, in other words, when the intensity of the flotation conditions necessary to produce flotation of the galena are less than those necessary for the flotation of the blende—to float any larger particles of galena that may be present it may be necessary to increase the intensity of the conditions to the extent necessary to cause the finer blende particles to float. When dealing with relatively coarse particles of galena and blende, differential flotation becomes difficult, this being probably due to the high specific gravity of the galena compared with that of the blende, which causes the ratio of surface to weight to decrease more rapidly with the former than with the latter mineral as the size of the particles increases. A process such as the Bradford would, to a limited extent, allow a somewhat larger latitude in the relative sizes of the galena and blende particles submitted for differential flotation. Fortunately, very little coarse galena gets past the gravity-concentrating machines and reaches the flotation units; in fact, in all products from tables, classifiers, etc., there is a natural tendency for the galena particles to be smaller than the blende particles, and this materially assists differential-galena flotation.

PREFERENTIAL FLOTATION. It was early recognized that it was possible to alter the surface of some sulphide minerals so as to reduce their floatative properties and still leave the surface properties of other associated minerals unaltered. Most of the research work, aiming at the separation of galena and blende, was directed along these lines prior to the establishment of the Lyster process. A low-temperature roast was used in the Horwood process,

and a lot of investigation was carried out to endeavor to obtain similar results by chemical means. The blende being a relatively stable mineral compared with the other sulphide minerals, it naturally followed that efforts were directed toward the alteration of the surface of the galena. Under this heading may be included the processes using oxidizers, such as ferric chloride, in hot acid solutions, and the Bradford acid-salt method, the latter attacking and altering the surfaces of the galena, some of the lead from which passes into solution as a chloride. All these processes are characterized by the blende being floated before the galena, and nearly always result in a zinc concentrate containing relatively high silver-values. This is no doubt due partly to the fact that the silver minerals, being readily floated, tend to rise with the first float, and is also partly due to the silver from any soluble silver salts formed by oxidation, etc., being precipitated on the blende. In view of the fact that only small payments are made for silver in the zinc concentrate compared with almost full value for any silver in the lead concentrate, it is of prime importance to recover as much of the silver as possible in the latter product. This phase of the question affected the economic position to such an extent that investigations on these lines were almost abandoned soon after the establishment of the earlier differential-galena flotation methods. One may safely state that these preferential methods would be applied to lead-zinc-silver ores only in special circumstances, and then only when differential methods of flotation had failed. With the exception of the Horwood process, none of these methods is now employed at Broken Hill.

MACHINES USED. The British Broken Hill Proprietary and the Zinc Corporation still retain the original M. S. type of machine, with separate mixing and spitz compartments, together with the underflow pipes. These machines give excellent service when a strong persistent float is produced, and have the advantage of the level of the pulp in each flotation compartment being under control. This control is of great importance when applying an acid treatment to ores containing varying quantities of calcitic materials, such as may be encountered when dealing with a mixture of material from several mines or tailing-dumps. In this case an increase or decrease in the quantity of CO_2 evolved reduces or increases the specific gravity of the pulp-gas-air mixture, and, unless the pulp-level in each cell can be independently maintained, it is difficult to control the froth-overflow. Apart from the gas factor, the single-level or staggered modification of this machine will, on fine material, give equally as good results as will the original type of machine with the underflow pipes. Boxes of the above types, even when reasonably crowded, do not allow of a rapid removal of the froth when formed, and are not favored in cases where a tender froth is produced. The term 'crowded' refers to a reduction of the area of the box toward the point at which the froth overflows, so as to increase the amount of froth reaching a given surface-area. This results in a quicker removal of the froth, and reduces the relatively dead surface-area away from the overflow-lip. The crowding should not be at too flat an angle, and

the lip should be on a vertical side of a box rather than over a 'crowded' side. The reason for this is that a larger amount of froth reaches the surface close to the crowded side, and this keeps the froth over the whole of the surface moving toward the lip, besides which the pulp at the surface close to a crowded side of a box is more agitated by ebullition than that at a vertical side, so that, if the lip is placed in the latter position, the chances of gangue being carried over mechanically are reduced.

The Central mill has adopted a single-level type of machine, in which the float is taken off the top of the mixing-compartment. In this case the necessary air is drawn in below the impeller, and the 'still zone', necessary to allow the mineral-charged bubbles to rise to the surface, is produced by baffles arranged above the agitation zone. A modification of this type of box is to be seen at the British mine, North mine, and the Zinc Corporation differential slime-plants. In these instances the air is drawn through hollow over-driven vertical spindles operating more or less shrouded impellers near wearing-plates at the bottom of the boxes. The 'horizontal' type of box has gained considerable favor of late, especially for slime flotation, and is now used for slime treatment at the Junction North mine and Amalgamated Zinc works, and for all flotation purposes at the Block 10 mine. Several of the other mines are contemplating the installation of this type of machine in place of the existing ones. This machine gives good results, but the horse-power consumed per ton treated is on the high side. Centrifugal pumps delivering into crowded spitkasten boxes are still favored at the Broken Hill Proprietary mill, but, although this type of machine was for a time used to a certain extent in some of the other mills, they have since been replaced by machines of other types. One company uses a modification of the Owen machine for differential slime-flotation, but, owing to the exceptionally high power-consumption per ton treated it is questionable if this is the most economical type of machine.

CASCADE BOXES OR POTS. This system, originally introduced by H. V. Seale and W. Shell-shear at the Junction North plant, has been applied, for differential flotation, in a portion of the Central mill, and for blende flotation at the Amalgamated Zinc plant. Although, at first glance, this machine would appear to reduce considerably the power necessary for flotation, this is only true to a limited extent. When an ore, prior to reaching the flotation machines, has received almost sufficient agitation to produce flotation, the cascade machine will yield a satisfactory float, but in other cases additional agitation must be provided before passing on to the cascade unit. As in the case of the pneumatic machines, the cascade pots will only give an incomplete recovery, unless the minerals are sufficiently prepared beforehand. Pneumatic machines have been tried experimentally by a few of the mining companies, but they failed to give satisfactory results.

SCOPE OF DIFFERENTIAL FLOTATION. With the successful establishment of differential flotation, the opinion was expressed by some that Broken Hill milling practice would sooner or later be revolutionized by a general replacement of gravity-concentrating machines (such as

jigs, tables, and vanners) by flotation methods. Flotation quickly displaced the vanners and tables operating on slime and fine mill-products, the recovery of the slimed galena from which had previously been a bugbear. It must be remembered that the galena that could not be recovered by tabling was in a fine state of division, and was, therefore, in an ideal state for differential flotation. Owing to the ease with which the coarser galena particles can be recovered by gravity concentration, and to the difficulty of differentially floating such particles, the local mills still retain their jigs and Wilfley tables for primary treatment. In the Central mill cascading has replaced all of the primary tables, and the tailing from the former is lower than that previously yielded by the Card table. Rasmus J. Harvey has shown that the galena in the feed treated is all comparatively fine, and that that recovered from the cascade plant is much finer than that previously recovered by the tables. This means that the galena in the tailing from this section is coarser when cascading is used than when the tables were used; but this galena, passing on to the zinc section, would be recovered more readily in their 'de-leading' tables than galena in a finer state of division.

No doubt a certain amount of the work at present done by tables for the recovery of fine galena will ultimately be performed by flotation, and, in view of the fact that in a hydraulically classified product the galena particles are smaller than the blende particles, close classification should assist in bringing this about. On the other hand, jigs and tables are not expensive machines to run; they make good recoveries of the coarser galena in a concentrate that contains less blende than an equivalent flotation product, and the concentrates produced by the former methods are more easily drained and handled than those produced by the latter. In the light of present knowledge I am strongly of the opinion that the major portion of the gravity concentration now practised at Broken Hill will not be replaced by flotation.

The successful application of collective flotation for separation of the sulphide lead-zinc-silver minerals from gangue has been responsible for a revival of investigations of leaching methods for the recovery of lead and silver. Much research work with various solvents was carried out at the Broken Hill Proprietary prior to 1900, but, owing to high operating costs, such processes could not be economically applied to the relatively low-grade mill-products. Now that it is possible to obtain high-grade mixed sulphide products containing very little gangue, the possibilities of these methods have been greatly increased. The solution of the galena never did present any serious difficulties, and it is now claimed that high extractions of silver can be obtained in the presence of unaltered blende. These methods, yielding a much more complete separation of the lead and silver from the blende than that obtained by any of the known differential or preferential flotation systems, will, with further development, be able probably to compete with flotation methods in many instances. The high operating costs of the solvent methods will, however, to a certain extent offset the increased lead and silver recoveries, and the

scope for such systems can only be determined by economic results. Undoubtedly there is room for both systems in Broken Hill, and the solvent methods should be of special advantage for treating slime-mixed concentrate or slime-middling, which products are usually rich in silver.

Reference must be made to copper sulphate, the use of which has considerably increased during recent years. Although originally specified in a patent of Bradford's, it was not, so far as I am aware, used commercially in Broken Hill until 1916. Small quantities of copper or any of the highly electro-negative metals, such as gold, platinum, silver, and mercury, are rapidly precipitated from solution when added to a pulp containing galena and or blende, and, while in the case of freshly-broken galena no increase in the flotative properties is noticeable, an appreciable enhancement in the flotative properties of the blende ensues. This enhancement is usually sufficient to bring about the flotation of fine blende particles in neutral or alkaline circuits under conditions suitable for differential galena-flotation, but not sufficient to promote flotation of coarse blende without the addition of some strong intensifier, such as acid. It has been found, however, that the addition of about 0.1 pound of copper in a soluble form to an ore containing about 14% zinc will allow the blende to float with less acid than would otherwise be required. This is of special value when treating calcitic ore, and the practice at the zinc concentrator of the Zinc Corporation may be instanced, where tailing that would require 60-70 lb. of acid per ton under ordinary mineral-separation conditions needs only 25 lb. of acid to promote blende flotation after the addition of about half a pound of $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$ per ton. All the copper added is precipitated and removed with the blende, so that the return-circuits are suitable for differential galena-flotation, if desired. Many of the parts of the earlier laboratory-flotation machines were constructed of copper or alloys containing copper, and small quantities of this metal passing into solution were no doubt frequently responsible for apparent anomalies between results obtained by different experimentalists. This factor probably retarded the discovery of many of the differential galena-flotation methods.

FLOTATION OF OXIDIZED ORES. So far, little has been done on a commercial scale in this respect, but at least two mills have in view the recovery of oxidized lead from dump material. As far as I know, the systems proposed include the superficial sulphiding (by H_2S , Na_2S , or similar reagent) of the oxidized galena, and the subsequent flotation of the same after the recovery of unoxidized galena and blende by ordinary methods. This method might be classed as a preferential method. It may be noted that the blende has higher flotative properties than the superficially re-sulphided lead minerals, so that the 'lead' float is the last to be taken off. Unless there is sufficient unoxidized galena to allow a primary float of this to be made, it appears as if there would be a tendency for a lot of the silver to find its way into the blende product.

CONCLUSIONS. I have endeavored to explain some of the

phases of froth flotation, especially as applied to local ores, from a practical point of view. Those who are closely associated with flotation work in Broken Hill will find that this paper contains nothing that is "new", but, as previously stated, any new discoveries in flotation have, to date, always been first described and published in patent specifications. Of recent years the practical side of flotation knowledge has made great strides, but many phenomena have not yet been satisfactorily explained. From time to time numerous theories have been advanced to try and explain certain flotation phenomena, but rarely, if ever, has a successful flotation process been evolved except by flotation experiments on a 'hit or miss' principle.

Strontium

Strontium is used in the form of its salts in several industries, especially in the manufacture of fireworks, drugs, and medicine. The principal salts manufactured in the United States in 1918 were strontium nitrate (SrN_2O_6) and strontium carbonate (SrCO_3), which are used chiefly in the production of red fire or light in pyrotechnics, flares, fuses, signal shells, and signal lights. Small quantities of chloride and oxalate were reported manufactured from crude ore in 1918. Many other salts were probably manufactured, but mostly as secondary products from the primary salts above mentioned. The acetate, lactate, bromide, iodide, arsenide, phosphate, and other salts of strontium are used in drugs and medicine. In Europe large quantities of oxide and hydroxide of strontium are used in refining beet sugar, but this process is not at present employed in the United States. A small quantity of strontium is alloyed with copper in making castings to free them of blow-holes caused by included gases. Fireworks and signal lights are manufactured in the United States almost exclusively near the Atlantic seaboard, and the demand for crude ore is therefore in the Eastern States. It has been difficult, consequently, to find a market for the domestic strontium ore, the workable deposits of which have so far been found only in the far West and which cannot in normal times compete in price with the celestine obtained from England because of high freight charges unless it is protected by a tariff. The known workable deposits of strontium ore in this country are in Arizona, California, Texas, Utah, and Washington. Other deposits of doubtful value occur in several other of the Western States and in a few States east of the Mississippi river. A new find has been reported from Utah, 25 miles south-east of the town of Green River, Grand county. J. T. Pardee, geologist, of the U. S. Geological Survey, reports that at this place celestite forms lenticular beds six inches thick associated with gypsum and limestone in the middle of the St. Elmo formation at the Colorado Fuel & Iron Co.'s manganese mine. Samples of the minerals are of excellent grade. In Nevada, 7½ miles south of Goldfield, large deposits of strontianite are reported to have been discovered by G. L. Dillenbaugh, of Goldfield.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

RAY CONSOLIDATED REPORT.

The Ray Consolidated Copper Co. has published its 35th quarterly report covering the operations for the first quarter of 1920. The gross production of copper was 11,650,443 lb., as against 11,660,923 for the previous quarter. There was milled 430,000 dry tons, averaging 1.707% copper, with an extraction of 78.65%, as compared with 397,100 dry tons, 1.813% copper, and 80.66%.

The carrying price of copper was 21.96c. per pound, owing to sales being in excess of production. Since the beginning of dividend disbursements, Ray has distributed to its stockholders a grand total of \$24,229,736.

COLORADO

NEWLY CONSOLIDATED COMPANY TO MAKE ZINC OXIDE.

LEADVILLE.—The Western Zinc Concentrating Co. and Leadville Zinc Co. have been consolidated as the Western

RAY CONSOLIDATED MINE, AT RAY, ARIZONA

respectively, for the last quarter of 1919. The underground development during the quarter totaled 11,100 ft., making the grand total of such work 753,192 ft. The mining cost for the quarter was \$1.69 per ton, of which 6.075c. was the cost of coarse crushing and loading, leaving a net mining cost of \$1.63, as against \$1.62 the previous quarter. The milling cost was \$1.25 per ton. The average cost per net pound of copper produced was 16.745c., as compared with 16.574c. during the previous quarter. Miscellaneous income, including gold and silver, was equivalent to 0.445c. per pound. The total profit for the quarter was \$637,300, and after payment of a dividend of 25c. per share on March 31, or a total of \$394,295, there was a surplus of \$243,005, as compared with a deficit of \$141,364 for the last quarter of 1919.

Zinc Oxide Co., with Charles H. Collins, president; C. J. Walker, vice-president; J. B. McDonald, treasurer; and H. L. Noble, secretary. Jesse F. McDonald and E. C. Granberry complete the directorate. The company will have available for treatment one of the largest zinc-oxide orebodies in the Leadville district. It is estimated that there are 60,000 to 100,000 tons partly blocked out in the Down Town Mines property and other mines may be expected to furnish their quota. A block of 16 furnaces is being added and when completed the plant will have 34 furnaces in operation with a capacity of 100 tons daily. The new unit will be in operation by August 1 and the plant will then be the largest producer of zinc oxide west of the Mississippi river.

Contractors have commenced work on the first 350 ft.

W. A. 1200-ft. contract let by the National Mining & Development Co. in the Chicago tunnel, at the head of Iowa grade. The property secured by the company consists of six claims, lying above the old Long & Derry mine. The tunnel is now in 915 ft. and is projected to cut the vein on the Ready Cash that outcrops 30 ft. wide at the surface.

The Pensardin on the west slope of Yankee hill under lease to E. Bowden is making occasional shipments of lead carbonate and sulphide ores to the A. V. smelter. Jesse F. McDonald, general manager for the Down Town Mines, reports that several small bodies of ore recently were opened and that the company is shipping about 48 to 20 cars weekly. The Penrose mine in the Down Town basin continues fair production of iron and lead carbonate and zinc.

IOWA SPRINGS.—A local leasing pool has opened up silver-gold-copper-lead ore on the Turner of the Freeland group. Samples assayed 1.36 oz. gold, 12 oz. silver, 45% lead, and 2.20% copper. The Newton and Hudson mills are in operation and the Combination mill is being overhauled to treat Specie mine ore. Operations are shortly to be resumed at the Refuge mine where a small force is making surface repairs and cleaning up.

GILLES COUNTY.—High-grade gold-silver-lead ore has been opened by the Midwest company and tests made at the Iron City mill on ore from the Peru vein, gave results of 25.68 oz. silver, 0.42 oz. gold, and 69.82% lead for first grade, or \$166.83 per ton. Second-grade ore milled 3.20 oz. gold and 3.40 oz. silver; total value \$67.87 per ton at current metal prices. The Midwest is testing ore from the Cyclops dump at the Iron City mill and if proved profitable will treat the entire dump. Operations have been resumed on the Cornucopia on Silver creek. Ore is under development by a winze from the tunnel-level and a mill is planned when orebodies in the tunnel and shaft workings are further developed. Nebraska owners of the Boss tunnel, in the Quartz Valley district, have a force of men at work and have re-timbered the 1416-ft. tunnel where necessary. The tunnel is to be connected by raise with the shaft workings, that when last worked in the early 80's, produced high-grade silver ore. A sample recently taken assayed 186 oz. Denver men interested in the Spur Daisy group are constructing a shaft and power-house on the Clare Marie claim. Machinery is to be put in and the shaft, 125 ft. deep, is to be sunk to 250 ft. The group is controlled by Boston capitalists, and was a rich producing silver property in early days.

CHIPLE CREEK.—Dividend No. 86 of the Cressen Consolidated Gold Mining & Milling Co. of 10 cents per share, \$122,000, has been declared payable June 10 to stock of record May 31. With this distribution stockholders will have received \$8,613,162. The Free Coinage Consolidated Mines Co. plans to cross-cut from the 1100-ft. level of Delmonico shaft, to traverse the Free Coinage property cutting under the Pinto shaft at 1500 ft. The cross-cut will intersect the Wilson, Pinto, and Pueblo veins of the Free Coinage system and two basalt dykes. All have produced from shaft workings, in excess

of \$2,500,000 gross from above the 500-ft. level. Bids have been advertised for 780 ft. of cross-cutting. The Delmonico shaft is equipped with powerful hoisting plant and compressor which will be used by the contractor. The Empire State shaft-sinking contract has not yet been let by Isabella Mines Co. management. The shaft is to be sunk from 1100 to 1500 ft. on this Bull Hill property.

OURAY.—A four-foot vein, new to the property, that contains 14 in. of ore sampling 428.8 oz. silver, 4 oz. gold, and 36% lead has been exposed by a cross-cut in the Hidden Treasure tunnel. The property, owned by the Walsh estate, is controlled by Mrs. E. B. McLean, daughter of the late Thomas Walsh. This is the second vein uncovered since work was resumed. Approximately 700 tons of ore, now stored, will be shipped as soon as road conditions permit. Half of the ore mined from the first Hidden Treasure vein is of smelting grade. A four-foot vein of silver-bearing quartz has been uncovered just below the surface on the Silver Spur property on the Slide vein extension, west on the Silver Spur property below town, by Mitchell and Zanin, of Ouray, operating under bond and lease. Contractors have commenced work on a 500-ft. shaft-sinking contract recently let by the Mountain Top Mining Co. Nine men are employed on the work.

GEORGETOWN.—New machinery will be placed in the mill of the Liberty Mines Co. at Argentine Pass and operations are to be resumed in the Pennsylvania mine in charge of E. LeNeve Foster, recently appointed general manager. Ore from the Turner mine at Freeland, under lease to B. A. Hedley, of Clear Creek county, from a 14-in. streak, assays 70% lead, 2 oz. gold, and 2 oz. silver.

MICHIGAN

QUINCY IS STOPING ON THE 77TH LEVEL.

HOUGHTON.—While the deal has not been actually concluded, the terms have been arranged and all details have been completed for the transfer of the Michigan Land & Iron Co. interests to Henry Ford and associates of Detroit. This involves 32,000 acres of upper-peninsula territory in Baraga, Houghton, and Iron counties. It comprises large tracts of hardwood timber land, with some mineral prospects, including two partly explored iron-ore deposits and a good deal of frontage on Lake Superior. The consideration runs into millions of dollars, it is reported.

The Michigan Land & Iron Co. is owned in England. Eighty-five per cent of the stock belongs to Lord Brassey. Originally the land was secured through some grants that were made in the early days of railroad-building in the upper peninsula of Michigan. The original Marquette, Houghton & Ontonagon railroad, now included in the Duluth, South Shore & Atlantic system, which company, in turn, is dominated by the Canadian Pacific interests, issued a large amount of bonds for its first financing. Covering the bonds was a land mortgage which the Brassey interests later found it necessary to take over. This land has been held by the Lord Brassey

people for 45 years. The Brassey interests are actively associated with mining developments in many parts of the world.

The Quincy's development of the east branch of the Pewabic lode continues to be the most encouraging sign for the future successful operation of this property. While the so-called east branch has not been extensively opened in the most northerly shaft, on the other hand, in the southerly shaft, at great depth, in No. 2, is shown the best copper 'rock' of any of the openings. At the extreme depth on the 73rd and 77th levels, both north and south of the shaft, the stopes are in good material. North of the shaft the lean zone from the 71th to the 77th levels, formerly opened in a kind of 'rock' which

the sale of 30,000 acres of timber land in Keweenaw county has not been completed as yet, but the details have been arranged and the announcement is expected at any time.

NEVADA

INTERESTING LAW-SUIT INVOLVES THE WALL STREET COPPER COMPANY'S PROPERTY.

COPPER CANYON.—George B. Thatcher, former attorney-general of Nevada, and associates plan to sell to George Wingfield the Homestake and Guy Davis placer claims in the Copper Canyon district, 20 miles south of Battle Mountain. Engineers have estimated the claims to be worth \$200,000 to \$400,000. The claims were

WARD, COLORADO

had every indication of going from bad to worse, now shows signs of improvement. Good stopes which were opened in January and February now are getting into better ground. Quincy's No. 6 shaft has opened stopes on the east branch and in the foot of the east branch produced rock of a quality that is better than the average of the Pewabic in the levels above the 73rd. In the 75th level, on this same east branch, is found the best-looking rock that now is coming from No. 6. This shaft is now being sunk below the 77th, which is the bottom level. Stopping is under way on the 77th.

Copper shipments continue by railroad and by boat from the Calumet & Hecla docks. The rail shipments are for foreign export. There is not likely to be an increase in production of copper from the Isle Royale mine this month, owing to the fact that the shipments have been just enough to keep the three-head Isle Royale stamp-mill operating. Hancock shipped 1000 tons of rock last week. Superior 900 tons. Keweenaw's deal for

located in 1913. The locations covered the lode claims Glasgow and Western, and this company secured an injunction restraining the prospectors from working the placer ground. The prospectors interested Thatcher and he fought the case for six years, finally securing a decision in his favor from the Supreme Court. When this decision was given the prospectors had all sold their interests to friends of Thatcher, principally State officials. There is no water flowing in the canyon, but other conditions are good, as the bedrock is smooth and there are few boulders. Shafts are being sunk to put the claims in condition for an examination by one of Wingfield's engineers. The bedrock is 40 to 50 ft. from the surface and the gold is found over an average width of 125 ft. The claims extend along the canyon 2400 ft. Where the channel is narrow the average value of the sand from the surface to a point three feet above bedrock is said to be 75c, and in several places on bedrock assays of as high as \$50 per yard have been secured. No attempt has been

made to secure a close estimate of the average value per yard of the deposit.

TOLICHA.—A 12-ft. width of gold ore assaying \$50 has been found in a 115-ft. tunnel cutting at shallow depth a vein in the Landmark group, being worked by T. A. Harney of Chicago and associates. In another vein in this tunnel there is a 17-ft. width that assays \$18. The Landmark is near the three Life Preserver claims that were developed under option several years ago by George Wingfield. Wingfield relinquished his option because of the refusal of the owners to extend the time and little work was done in the district until Harney secured an option on the Landmark several months ago. The vein material is silicified rhyolite 5 to 20 ft. wide, with rhyolite walls. Most of the ore assays \$25 to \$50, but rich ore has been found by Harney in the last month. Air-drills are used and six miners are employed. Drifts are being driven from the tunnel and a shaft will be sunk and the ore blocked out in preparation for the erection of a mill. The ore is not refractory and tests may be made with a pan-amalgamation plant. Tolicha is 50 miles south of Goldfield and is 12 miles from a railroad.

SPRUCE MOUNTAIN.—The 30-ton smelter of the Bullshead Mining Co. in the Spruce Mountain district of Elko county is to resume treating silver-lead ore from the Bullshead mine, and custom ore. A water-jacketed furnace is used and the fuel is 60% mountain mahogany, plentiful in the vicinity, and 40% coke. The smelter when operated last fall produced at a rate of ninety 100-lb. bars of bullion in 24 hours. The average value of the ore treated was \$45 per ton. The district is in the Spruce Mountain range and heavy snow makes the hauling of supplies and ore difficult in the winter. The mine and smelter will be in charge of Walter Palmer, a professor in the Mackay School of Mines at the University of Nevada.

AUSTIN.—Hubert W. Rast has contracted with a San Francisco paint company for the output of ochre from his mine near Walters station on the Nevada Central. Ochre, the earthy form of hematite or limonite, is used as a pigment in the manufacture of paint. The price to be paid Rast is \$30 per ton f.o.b. Walters station. The ochre is found in veins containing seams of silver-lead ore.

GOLDFIELD.—The case of M. B. Aston against C. R. Evans, congressman from Nevada; A. H. Howe, a Reno broker, who formerly was secretary for the Goldfield Consolidated, and W. S. Norris, connected with several Nevada mining companies, is to be tried in the district court here. Alleging deception and fraud, the plaintiff seeks to recover 37,500 shares of stock in the Wall Street Copper Co. and a share in the war-time profits of the company. Aston claims the net sum due him is \$60,000. The "shooting" of the drill-holes so that he could not enter the mine, the covering of faces of good ore with broken material, and similar tactics are charged against the defendants in the complaint in what Aston claims was a successful attempt to secure his interest for \$15,000. The complaint says Aston sold his interest in 1913. The defendants in their answer deny all of the material alle-

gations. Well-known lawyers have been employed by both sides and it is rumored that much "dirty linen" will be washed during the trial. The plaintiff claims \$625,000 as the gross value of the ore produced. The defendant places this amount at \$600,000 and the expenses at "over \$167,000". These figures are for the output from June 10, 1916. Ore from the Wall Street was taken from the mine by pack trains and then loaded into wagons and hauled to the railroad.

VIRGINIA CITY.—The United Comstock Mines Co., capitalized for 5,000,000 shares, par value \$1, has been organized to build a 1000-ton mill to treat low-grade ore from the Gold Hill mines of the Comstock. Bulkeley Wells, president of the American Mining Congress, George Wingfield, and Herbert Humphrey are said to be the main factors in the company. The upper levels of the Gold Hill mines have been re-opened and sampled and it is reported that several well-known engineers have approved the plans to treat the ore on a large scale. A complete statement is expected in a short time from the new company. This will be the second attempt in Nevada in recent years to treat on a large scale low-grade gold ore in old mines. The first was the Goldfield Development Co., operating the Consolidated mines at Goldfield. This company, after over a year of financial difficulty, is to start early in June ten stamps of the 1000-ton mill. The objective is the treatment of 1500 tons of \$5.60 ore daily. The fate of the McFadden bill is of importance to Virginia City and Goldfield, as in both places there are millions of tons of gold ore that can be treated at a good profit if a better price can be secured for the metal.

COMO.—The Como Consolidated company is treating daily 100 tons of gold-silver-copper-zinc ore assaying \$10 to \$12, and bullion shipments are being made at a rate of \$25,000 to \$30,000 per month. At a special stockholders' meeting, at which 932,000 of a total of 998,000 shares was represented, it was decided to issue 35,000 shares of preferred stock at \$10 to pay for the recently acquired claims of the Buckeye Gold & Silver, Rapidan Silver, Mountain Belle, and Palmyra Tunnel Gold & Silver companies. The purchase of the claims of the last gives the Como a tunnel 4500 ft. long that can be extended to cut the Buckeye and Rapidan veins at a depth of more than 600 ft., or 300 ft. below the present workings. Part of the funds from the stock issue will be for equipping and continuing the tunnel. The driving of the tunnel into the veins will eliminate expensive pumping. The Buckeye shaft has levels at 115, 200, and 300 ft., the drifts reaching a depth of 50 to 75 ft. more than the shaft levels. The average width of the vein is 10 ft., with an extreme width of 50 ft. A drift has been driven 175 ft. north-east on the bottom level without reaching the limit of the ore-shoot, which is 12 ft. wide at the face. Some of the material in this drift is unusually rich in silver and gold. Drifts south-west from the shaft have opened ore for 875 ft. The vein in the Rapidan, north of the Buckeye, strikes almost at right angles to that in the Buckeye. The inclined Rapidan shaft is 350 ft. deep. An ore-shoot of an average width of 10 ft. has been

opened for 775 ft. on the bottom level and ore is now being broken for a width of 15 ft. in a stope north of the shaft. The average value of the Rapidan orebody is estimated to be \$10 to \$12. In the Lucky Sunday, south-east of the Buckeye, ore of higher than average grade is being developed at a depth of 100 ft. This shoot, 5 to 10 ft. wide and assaying \$75, had been opened for 135 ft. when work was temporarily discontinued recently because of the poor condition of the road to the mine.

NEW MEXICO

CHINO COPPER CO.'S REPORT.

During the first quarter of 1920 the Chino Copper Co. milled 413,900, equivalent to 4548 tons per day, as against 4832 tons per day for the previous quarter. The

deficit of \$161,858 during the previous quarter. Earnings for the quarter were computed on basis of 21.88c. per pound for copper, due to sales being in excess of production. The steam-shovels at Santa Rita moved a total of 569,479 cu. yd. of stripping during the quarter.

UTAH

PRICE OF SILVER IS HURTING UTAH MINES.

SALT LAKE CITY. The decline in price of silver to the \$1 mark has caused considerable uneasiness among the silver-lead mining men of the State. There is no question but that \$1 per ounce is a good price for silver under normal conditions, but right now conditions are far from normal and \$1 is little better than was 50c. some years ago. The mining industry is struggling along

THE TONOPAH DIVIDE MINE

average grade of the ore was 1.83% copper, as compared with 1.77% for the last quarter of 1919. The total quantity of copper produced was 10,621,276 lb., as compared with 9,821,729 lb. for the last quarter of 1919. The recovery per ton of ore milled for the first quarter of 1920 was 25.66 lb., as against 22.09 lb. for the last quarter of 1919. The concentrate production was 32,606 dry tons, averaging 16.29% copper, as compared with 31,641 tons and 15.52% copper for the previous quarter. The cost per pound of copper produced, including all charges except Federal income and excess profits tax, was 14.62c. per pound, as compared with 18.65c. for the last quarter of 1919. Allowing for gold and silver credits and miscellaneous income, totalling \$72,122, or 0.71c. per pound, the net cost of production was 13.91c. The total profit for the quarter was \$809,727, and after payment of a dividend of 37½c. per share, or a total of \$326,243, the net surplus was \$483,485, as compared with

under serious handicaps of high taxes, inefficient and high-priced labor, and greatly increased costs of every item entering into mining, milling, and smelting. Not only this, but a decline in the price of silver means a smaller production, because ore that could be marketed at a profit with silver above \$1.25 per ounce, must now be left in the mine. Utah ranks third among the silver-producing States in the Union, and the decline has caused heavy losses to the large operators. For instance, the Chief Consolidated mine at Tintic is suffering a loss of between \$70,000 and \$80,000 per month by reason of the decline, as compared to the prices of silver prevailing at the beginning of the year. Other mines in Tintic and Park City are suffering in like manner.

Announcement was made on May 27 by Carl A. Allen, district engineer of the Bureau of Mines, that the date for mine-rescue and first-aid contests at Denver have been postponed from August 20 and 21 to Sep-

8, 9, 10, and 11. The contest this year will be international, with teams from Canada and Mexico competing. It is expected that Utah will send at least two teams to the contest from the Utah Fuel Co. and United States Fuel Co.'s forces, and one each from Bingham, Park City, and Eureka.

PARK CITY. J. D. Fisher, superintendent, reports that a full face of ore is exposed on the 1700-ft. level of the Naildriver mine, with every indication that a permanent body has been cut. On the 1500-ft. level an orebody is being developed that assays as high as 85 oz. silver per ton. The wagon-road to the property has been shoveled out and workmen are now engaged in building a culvert to take care of the water that has been diverted from its channel by the Ontario dump and doing considerable damage to the road. Soon after June 1 shipments will be started.

Ore shipments from the district for the week ended May 22 totaled 2263 tons, as against 2397 tons for the previous week. The Judge Mining & Smelting Co. shipped 655 tons; Silver King Coalition, 542 tons; Ontario, 512 tons; Daly-West, 175 tons; Daly, 155 tons; and the Judge smelter, 112 tons of premium spelter.

The ore encountered recently by the Silver King Consolidated company in its Spiro tunnel is described as occurring in a series of parallel stringers of galena crossing the tunnel a foot or two apart. The galena is high-grade and looks almost like the ore in the old shaft workings. While it is inferred that the stringers across the tunnel proceed from a mineralized fissure, the management does not believe the fissure to be one of the large bonanza veins which are the objective of the tunnel development. In this development the company is handicapped by the water which continues to flow from the breast, the broken-up character of the ground, and the difficulty of securing competent miners. The broken ground, although it slows down the work, is just the formation in which the probability of large orebodies is greatest. The tunnel is at present in more than 12,700 ft., and it is expected that another 250 or 300 ft. will bring it to one of the major south-west veins of the district.

EUREKA.—During the first quarter of 1920, the Chief Consolidated Mining Co.'s development work totalled 6298 ft., comprising drifts, raises, and winzes. The new No. 2 shaft was sunk a distance of 221 ft. during the period. Ore shipments totaled 22,996 dry tons, from which was produced 1518 oz. of gold, 651,453 oz. of silver, 2,911,174 lb. of lead, and 40,216 lb. of zinc. The silver-lead crude ore averaged 0.066 oz. gold, 28.33 oz. silver, and 11.5% lead. The average gross value of all ores was \$49 per ton, and after deducting smelting, freight, and sampling charges of \$19.82 per ton, the average net value was \$29 per ton. After payment of smelting, transportation, and sampling costs, the income from the above output was \$678,972, while the net profit for the quarter was \$188,522. A dividend of 10c. per share was paid, totaling \$88,123. Conditions in the mine are reported as being in a most satisfactory condition.

Shaft No. 2 is now being sunk at the rate of five feet per day. It is close to the 1400-ft. level, and has been in porphyry up to the present time. It is thought the shaft is nearing the limestone, in which formation better progress is anticipated.

Ore shipments from this district for the week ended May 22 totaled 141 cars, as against 170 the previous week. The Chief Consolidated shipped 39 cars; Tintie Standard, 20; Dragon Con., 13; Eagle & Blue Bell, 13; Iron Blossom, 8; Victoria, 7; Mammoth, 7; Grand Central, 6; Iron King, 5; Gemini, 5; Bullion Beck, 4; Centennial Eureka, 4; Colorado, 4; Empire, 2; Alaska, Godiva, Ridge & Valley, and Victoria Con., each 1 car.

The large boarding and lodging house at the property of the Tintie Empire Co. in the northern part of the district was recently destroyed by fire. The fire had made considerable headway before it was discovered, so that the occupants of the building lost all of their personal effects. The other buildings belonging to the company in that vicinity were saved.

The Ruby shaft of the Knight Drain Tunnel Co. is nearing the 600-ft. level, with conditions favorable for rapid sinking. The work is being handled under contract, and while the first few hundred feet were expensive, owing to the water developed, better progress is now being made. At the Big Hill property, development work has reached an interesting stage. A shaft has been sunk to the 600-ft. level, and a drift started which has for its objective one of the most important veins in that section of the district. This drift has been driven a distance of 200 ft., and after cutting across the vein, it is the intention to follow it both north and south, as the company officials expect important disclosures at points where it is intersected by east-west breaks.

AMERICAN FORK.—There is considerable activity this spring in the American Fork district. The roads have been cleared of slides and rocks and are in good condition as far as the Wild Dutchman mine. Mining outfits are going up the canyon nearly every day and many properties are working moderate forces, among them being the Belorophon, Lone Pine, Silver Flat, Treasure Hill, Pacific, and Silver Dipper, while the South Park, Pittsburg, and Silver Lake properties will shortly begin development work. The Belorophon is in good condition. Although the drift is about 20 ft. from the vein, every seam is full of lead and copper. The Pittsburg and Utah Centennial properties are both in shipping ore, but have been idle during the winter. At the Pacific mine, ore has been mined for several weeks past. A silver-copper stope has been opened, while a stope of lead milling ore is about ready for mining. There is a mill at this property, and operations are expected to be resumed before long.

BRITISH COLUMBIA

CONSOLIDATED M. & S. CO. PLANS TO DEVELOP COPPER PROPERTIES.

VICTORIA.—The fact that the Consolidated Mining & Smelting Co. proposes becoming one of the large copper

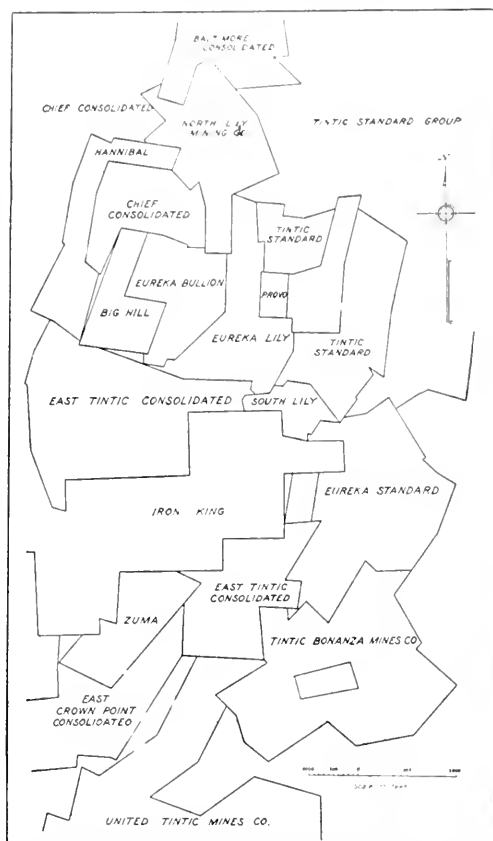

producers of the Province is becoming evident. The company has been laying the foundations to this end for some time. It has two large copper deposits on Vancouver island under development, one being the Old Sport, situated on Elk lake near the south east arm of Quatsino sound, and the other the Sunloch, at Jordan river not far from Victoria. Through surface work, diamond drilling, etc., some 1,500,000 tons of copper ore, approximating 1.8%, has been proved on the former property and it is authentically reported that reconnaissance surveys have been made of a number of railroad routes to tidewater. The company recently acquired control of the Sunloch where it is estimated that 2,500,000 tons of proved ore, averaging between 1 and 2% copper per ton, has been blocked out. The Big Interior group also has been bonded. It is situated at the head of Great Central lake at an altitude of 6200 ft. This season's work will consist of the securing of all possible information regarding its possibilities, the topography and geology of the area being investigated with a view to establishing the practicability of working the deposit from about the 1500-ft. level. If this can be done the problem of making a mine will be simplified. As to transportation, the E & N railway is to be extended from the town of Alberni to the south end of Great Central lake so that it will be a matter of running the ore down the mountain to the water, loading it in scows for transport over water for 22 miles, and dumping it in waiting freight cars for removal to the point selected for treatment. The Tidewater Copper Co. at Sidney Inlet is proceeding with the opening up of its deposits with satisfactory results. There are at least 500,000 tons of $1\frac{1}{2}$ to 2% copper ore proved with good prospects of larger quantities being developed as work continues.

Neither the Granby Consolidated Mining & Smelting Co., Hidden Creek, nor the Britannia Mining Co. are working up to capacity at present. In the old workings of the Britannia it is roughly estimated that there are 9,000,000 tons of ore in reserve and on the Victoria claim, under development, it is calculated that there are a possible 5,000,000 tons.

VANCOUVER.—By the staking of a mineral claim within the municipality of Point Grey and demanding that he be given title under the Mineral Act, James Adair, a prospector, has presented the Provincial government with a problem that promises to be difficult of solution. Adair asserts that he has a good showing of ore in a section, the residential popularity of which has given property considerable value. The terms of the Act, it is said, have been fully complied with but Adair's application for the completion of the record has not yet been approved. He declares that it is his intention to press the matter so that the courts may have an interesting point to settle.

STEWART.—It is reported that the line of railway up Bear river in the Portland Canal district is to be repaired and operated this summer. The Algonquian Development Co., Ltd., is reported to have made an arrangement with the Canadian Northeastern Railway Co. under the terms

of which the long deserted line will be put in shape and used for the transportation of supplies and equipment during the season. The work involves reconstruction of the Butter Creek and Bear River bridges, clearing a right of way, etc. Tenders are being called for. The Northern Light property is actively under development and diamond drilling is to be undertaken as soon as weather conditions render it feasible. Five thousand feet of this

MAP SHOWING PROPERTIES IN THE TINTIC DISTRICT, UTAH

work is planned. There has been much activity in the transport of supplies to the Spider property, Salmon river. Hauling was done on Yukon sleighs. A temporary camp has been established and a compressor-house is under construction. A three-drill compressor and engine is being placed. The tunnel-site is being cleared of snow and drilling will commence in a few weeks.

ALICE ARM.—The men who were sent by the Taylor Mining Co. to replace those on strike at the Dolly Varden mine, sided with the strikers on arrival, and refused to go to work. A more recent dispatch states that the strike is settled, but does not give the terms of the agreement. The McLennan Silver Mines, Ltd., has bonded the Royal

group of seven claims adjoining the Dolly Varden property.

Clyde A. Heller, of the Tonopah-Belmont Development Co., and George H. Garry, geologist, recently visited the Belmont-Surf Inlet property. The Belmont company has purchased the Prinrose Royal group, near the Surf Inlet property, and will start development at once. Like the Surf Inlet mine, the ore contains gold, silver, and copper. The main value of the ore is in the gold.

PRINCETON. Trains are again running between Princeton and Allenby on the Copper Mountain branch

HYDRAULICKING IN BRITISH COLUMBIA

of the Kettle Valley railway, but the construction work between Allenby and Copper Mountain is again tied up by another strike. The Canada Copper Corporation had expected to commence the shipping of concentrate to the Trail smelter in August, but how long the strike will delay the date is not known. Except for continued labor trouble this property would have been shipping and employing between 400 and 500 men several months ago. H. R. Van Wageningen, general manager for the company, has returned to Copper Mountain, after spending the winter at Denver.

ONTARIO

LABOR SHORTAGE SERIOUS AT COBALT AND PORCUPINE.

TORONTO. On May 19 new taxes, seriously affecting the Canadian mining industry, were imposed. The war customs duty of $7\frac{1}{2}\%$ was abolished, and the business profits tax considerably modified, profits not exceeding 10% per annum being exempted. The new imposts include a tax of 1% on all sales by manufacturers, wholesalers, jobbers, or importers (with the exception of sales of essential food, coal, and goods for export). The most drastic change affecting the mining industry is the imposition of a stamp tax of 2c. per share on each share of stock transferred, irrespective of the value of the stock, which will hit the smaller companies hard and, in the opinion of the mining brokers, will greatly curtail transactions and hinder the formation of new companies.

Strong protests have been made to the Government in the hope that the tax may be modified.

PORCUPINE.—There are renewed complaints of the shortage of labor and the restless uneasy disposition of the miners here. The output of the Hollinger Consolidated is stated to be declining, the tonnage treated having dropped to about 1700 tons daily as compared with the average of 1950 tons during 1919. Were they available the staff would be increased by 300 or 400 additional men. With a continuance of these conditions there is little prospect that the old dividend basis of 1% per month will be restored this year. The directors of the Clifton-Porcupine have laid out extensive diamond-drilling and contracts for several thousand feet of this work will be let immediately. Cross-cutting and drifting on vein No. 7 on the 200-ft. level are stated to have been attended with satisfactory results. The North Crown, the new company which has taken over the Porcupine Crown and Thompson-Krist, is asking for tenders for 1000 ft. of cross-cutting on the 500-ft. level to explore sections of the property lying west of the main vein. A good tonnage of milling ore is in sight at the 100-ft. level, from which the mill is being supplied.

MATACHEWAN.—Diamond-drilling to the depth of 1000 ft. has cut ore of good grade near No. 2 shaft of the Matachewan (formerly the Otisse). At No. 1 shaft a large tonnage of ore has been blocked out. The company is making preparations for the erection of a mill, the first unit of which will have a capacity of 100 tons per day. The Lake Matachewan, adjoining on the north-east, is preparing to explore what is believed to be an extension of the Matachewan's orebodies.

COBALT.—The Nipissing Mining Co. resumed shipment of bullion during the last week in May after having stored its silver for nearly two months. With quotations at around \$1 per ounce, plus exchange of from 10 to 13% on New York funds, the gross return is about three times as great as the cost of production, which during 1919 amounted to a little under 36c. per ounce.

Shortage of labor is becoming the outstanding problem which the Cobalt mining companies now appear to be obliged to solve. High wages in outside industries is gradually inducing men to leave, and at the majority of the mines the shortage is felt. The International Nickel Co. sent a representative to the silver camp and is offering wages a little higher than the Cobalt schedule. Meantime, the Cobalt companies have not intimated any intention to enter into competition in bidding against outside industries. They continue to pay the usual wage.

The Coniagas company is now drawing ore from its recently purchased Trethewey mine, and the investment should prove to be a profitable one. The Coniagas has also commenced work on a group of claims in the Gowganda district which were recently acquired under a working option agreement. Production from the La Rose Consolidated is heavier than during the corresponding period one year ago. Ore is being drawn from four of the company's properties, namely: the La Rose itself, the Violet, Princess, and University.

THE MINING SUMMARY

ALASKA

The wages paid to employees of the mines and mills in Alaska vary to some extent, being higher at Kennecott and Latouche, where expenses are greater than in the vicinity of Juneau where living costs less. One of the largest companies operating in the Juneau district maintained an average daily scale of \$4.87 during 1919 for eight hours, charging \$1 per day for board. At Kennecott and Latouche the average wage at present is above \$6, which includes a bonus of \$1.75 which will continue at least until July 1 of the present year, this bonus being based on the price of copper. Board at the latter places is charged for by the companies at \$1.60 per day, hospital charges 5 cents per day. Steady work is furnished by all the metal-mining industries of the Territory and all the employees are satisfied with the wages and accommodations. There are no labor troubles in any of the mining camps of the Territory. — The Cliff mine, near Valdez, from which gold to the value of nearly a million dollars had been taken previous to the closing down a few years ago, has been re-opened and will be operated. Other properties in the same locality are being prospected with a view to operating. At letter from Nome suggests that the tin deposits of that locality may be exploited soon. A shaft is to be sunk to a depth of 1000 ft., and cross-cuts will be run. If the property shows up as well as it is believed, a plant will be built.

CALIFORNIA

Calaveras County.—Unwatering of the Lightner mine shaft is progressing, and lateral work will soon be undertaken. The shaft will be sent several hundred feet deeper and new levels opened. The Lightner for many years ranked among the premier gold producers of the Mother Lode and is excellently equipped.

Nevada County.—All units of the 80-stamp mill of the Empire Mines Co. are now in operation and it is reported that satisfactory results are being obtained. No milling is being done at the Pennsylvania plant, the two having been consolidated. The underground crews of the Empire mine continue insufficient and very few men are applying for positions.

Plumas County.—It is reported that the Engels Copper Co. is negotiating for the purchase of the Thompson smelter from the Mason Valley Mines & Smelter Co. The plant is near Yerington and ranks among the largest copper plants in the West. The Engels company is the largest active copper-producing corporation in California, and operates important mines and a large flotation plant on the Plumas copper belt. It is further reported that a reverberatory furnace will be added to the two blast-furnaces for smelting of concentrate and custom ores.

Trinity County.—The Globe mine here will resume operations after lying idle for the past few years. A body of ore has been opened which is of sufficient extent to justify running the mill under present prices for labor and supplies. The Globe is one of the best equipped mines in the State in point of milling facilities. It recently changed hands, and the new owners have been running tunnels for the purpose of developing ore. A few years ago the mine

employed nearly 100 men. The Democrat mine has been sold by Junkans, Hanna & Ryan, local men, to H. E. Markley and L. Evans, of Marysville. The new owners have already put men to work clearing out the tunnels and getting the property in shape for operation. A mill is on the property. The ore in the Democrat carries free gold and is rich. The property lies on the dividing ridge between West Weaver creek and Democrat gulch, both of which were rich in gravel gold.

The mill at the Globe mine, near Dedrick, is being started up. A large quantity of ore averaging around \$20 per ton is in sight. The mill has been idle for several years. A. B. C. Cousin is super-intendent. The Globe mine is at an elevation of 6500 ft. The mill is 2000 ft. lower, mine and mill being connected by a tram 6500 ft. in length.

COLORADO

Ouray.—There is marked activity in the district, and numerous properties are now shipping; production will increase as weather conditions become more favorable. As the ores of Ouray are rich in silver, a steady market for this metal ensures prosperity for Ouray. — Carney and Kelleher have resumed operations on the Wedge, and are working over the old dumps. Shipments are being made. — Luna and Eckman continue to operate the Wedge through the Bachelor Keedive tunnel, getting out a rich silver ore. — The Black Girl is now being put into condition to ship. An output of 10 cars per month is anticipated. — McCarthy and Smith have leased the Wyoming, located near Red Mountain.

The White Cloud Mining Co. is opening up a three-foot body of ore, containing silver, lead, and copper. — The Hidden Treasure has a large amount of ore broken, which will be shipped as soon as the trail is passable.

Silverton.—The snow still remains in large drifts, seriously impeding operations, but the warmer weather of the past two weeks will no doubt result in rapid melting. Many of the mines have a heavy tonnage of ore broken ready for shipment. — The Gold King Extension Mines Co. has a large quantity of ore broken, and 20 cars of concentrate ready to ship as soon as the Gladstone branch of the Silverton Northern railway is opened. — W. Harrison will probably resume operations on the Pride of the West property, which has been idle for a year.

Lessees on the Ridgway have opened up a good vein of gold-silver ore, and shipments will be made this season. The Ridgway is an old producer, owned by the bondholders of the Eureka Exploration Co., but has not been operated for several years. Bonner & Co. carried on extensive development in 1914. — The Grand Meadows group, situated at Animas Forks, is being developed. — The Dives Leasing Co. and the Highland Mary have several cars of ore ready to pack out.

IDAHO

Coeur d'Alene.—The Hypotheek Mining & Milling Co. has cut a vein 170 ft. from the portal in its new tunnel. The vein has been penetrated for six feet and the drill-holes indicate that it must be wider. It contains only a little ore at the point of intersection, but the appearance

in the vein matter is good. According to a report from Kellogg, ore has been found in sinking a shaft at the Yankee Boy mine. A load of high-grade ore is said to be ready for shipment. A long cross-cut tunnel will develop the Yankee Girl property.

Lemhi County.—An electric-light and power plant is being installed on French creek, on the upper Salmon river, below Florence, to light the placer ground being developed. It is planned to run a power-line to the rich gold-quartz mines in the Bear Creek and Mount Marshall districts, which are being successfully operated and are shipping bullion from time to time. Mount Marshall lies on the south side of Salmon river, and the veins are regarded as a continuation of the lodes traversing the Buffalo Hump district, on the north side of the river.

Mackay.—Profitable mining from almost the first day of work has been possible upon the property of the Doughboy Mining & Leasing Co., situated five miles north-west of here, according to Arthur N. Sweet, consulting engineer. This property, consisting of four claims, was acquired by the Doughboy company only eight weeks ago. Now that the company has been organized the shaft will be sunk to a depth of 500 ft., and 1000 ft. of drifting on various levels will be done. The car of ore now on its way to the sampler averages 35% lead and 33 oz. silver per ton. At the bottom of the shaft, at a depth of 240 ft., there is 4½ ft. of ore, a sample of which averaged 65% lead and 69 oz. silver, according to Mr. Sweet.

MONTANA

Butte.—The Jardine Mining & Milling Co. has resumed operations under the management of H. C. Bacorn. Forty stamps are operating on a high-grade gold ore. The ore-bodies already blocked out are said to be extensive. Satisfactory milling results are being obtained. This property is located 6 miles from Gardiner. Twenty-one of the 26 claims owned by the company are patented. Present plans are for the treatment of 400 tons daily. Tungsten is also an important product of milling operations.

Nehalem.—The Cascade Silver Mines Co. is now milling between 200 and 250 tons of ore per day; 30 men are working three shifts. The mill concentrate assays 40 oz. silver per ton. An old dump running 10 oz. of silver is also being re-worked.

NEVADA

Gold Circle.—The Gold Circle Queen is making fair progress in sinking its shaft from the 230 to the 330-ft. level, a greater amount of water than was expected interfering somewhat. A telephone line has been run for 2½ miles to connect the camp with the main line. R. S. Holam is general manager.

Leadville.—The Leadville Mines Co. has cut on the 500-ft. level a vein in which six inches assays 280 oz. silver and 45% lead, while a sample over four feet assays 40 oz. silver. A test-run of the mill indicated the desirability of certain changes which are now finished. High-grade ore taken out in the development of the new vein is being sacked for shipment. A motor-driven compressor and hoist are being put in underground.

YUKON

Dawson.—The Yukon Gold Co. started its hydro-electric plant on May 26, and its fleet of dredges is in full operation. Individual miners have started to wash pay-ore that has been won during the long winter months. —After a long preamble, the following resolution was passed by the Yukon council, recently: "Be it resolved that in the opinion of this council the salary and living allowance of the gold commissioner, G. P. Mackenzie, should be increased substantially, and that in addition the Government should make provision for him to occupy government house."

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

J. O. Greenan, of Mina, Nevada, is at Berkeley.

H. R. Plate has left for New York, to be gone about two weeks.

F. W. Denton, of Cambridge, Massachusetts, is at Painesdale, Michigan.

L. C. Graton is with the Calumet & Hecla Mining Co., at Calumet, Michigan.

James M. Platt has left Mexico City and is now at Santa Barbara, California.

Oscar Lachmund, of Spokane, is leaving for the Orient on professional business.

Howard W. Fitch was married on June 2 to Miss Mary Marshall of Salt Lake City.

C. W. Beauchamp has become mill-foreman for the Harmony Mines Co. at Baker, Idaho.

Herbert C. Enos is assistant-general manager for the El Oro Mining & Railway Co., at El Oro, Mexico.

Frank L. Stack has left for Mexico to accept a position with the Santa Gertrudis Mining Co., at Pachuca.

R. F. McElvenney, manager of the Garfield smelter of the A. S. & R. Co., has returned to Utah from New York.

O. M. Knicks, general manager of the International smelter at Tooele, has returned from New York to Salt Lake City.

W. O. North has left Nevada to accept a position as consulting engineer to the La Fe Mining Co., at Guadalupe, Mexico.

E. N. Wanamaker and **E. A. Reinoso**, of the research department of the Anaconda Copper Mining Co., were in Utah recently.

Robert T. Hill has joined **J. Edward Brantly** and **R. S. McFarland** in a partnership as geologists and engineers at Dallas, Texas.

Henry Lyne, for many years head of the ore-purchasing of the A. S. & R. Co. at Denver, has been taking a holiday at Santa Barbara.

Thomas Carmichael, who has been connected with the Chief Consolidated Mining Co. for a number of years, has been appointed treasurer of the company, to succeed **W. P. Seager**, deceased.

H. C. Plummer, formerly assistant-superintendent of mines for the Cananea Consolidated Copper Co., at Cananea, is now superintendent for the Arizona Commercial Mining Co., at Globe, Arizona.

Chas. Butters & Co. has opened offices at 90 West St., New York, to be under the direction of **F. L. Bosqui**. Also at Salt Lake City a complete engineering and ore-testing laboratory has been opened under the supervision of **A. H. Jones**.

A. C. Boyle, Jr., for the past ten years Professor of Mining, Metallurgy, and Economic Geology in the School of Mines, University of Wyoming, has resigned to accept the position of geologist for the Union Pacific Railroad Co. For the present he will be stationed at Laramie.

Frederick G. Cottrell, recently nominated Director of the U. S. Bureau of Mines, received the Willard Gibbs medal from the Chicago section of the American Chemical Society. This medal, named for a distinguished American scientist, was founded by William A. Converse, of Chicago, and is conferred in "recognition and encouragement of eminent research in theoretical and applied chemistry".

THE METAL MARKET

METAL PRICES

San Francisco June 1

Aluminum dust, cents per pound	6 1/2
Antimony, cents per pound	10
Copper, electrolytic, cents per pound	19
Lead, pur. cents per pound	8 75-9 75
Platinum, pure, per ounce	\$95
Platinum, 10% iridium, per ounce	\$130
Quicksilver, per flask of 75 lb.	\$80
Silver, cents per pound	0.50
Zinc dust, cents per pound	12 50-15 00

EASTERN METAL MARKET

(By wire from New York)

May 31—Copper is inactive and steady. Lead is quiet and firm. Zinc is dull but easy.

SHAR

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 3, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine) calculated at the normal rate of exchange.

THE BUSINESS CYCLE

In the June number of its publication, "Commerce Monthly", the National Bank of Commerce of New York explains the "business cycle" and shows its relations to industry and finance. It says:

"The normal business cycle, as it occurs in the absence of special disturbing factors like a great war, has been carefully worked out by a number of recent writers. The description may start at any place in the business cycle, and the analysis will work around again through the cycle to the starting point. It is convenient to start with the close of the period of depression.

"At the end of a period of depression we find the following situation: (1) prices are low; (2) there have been drastic reductions in costs; (3) the margins of profits are narrow; (4) bank reserves are high; (5) conservative policies obtain as to borrowing, capitalization, and loans; (6) stocks of goods on hand are moderate; (7) buying is cautious. In such a situation an expansion in the physical volume of production and sales takes place, often with prices still falling. During the period of depression which is coming to a close, people have used up their stocks of clothing and shoes, have reduced the volume of household furnishings, linen, china, and the like, factories have allowed equipment and stocks of raw materials to get as low as seems wise, and new buying is forced upon everyone who is in a position to undertake it. Moreover, a growing volume of conservative business men and investors who had 'sold out' on the crest of the preceding wave of prosperity, have reached the conclusion that things have about reached bottom and are disposed to invest or to start business again. There comes then a slow and cautious revival and expansion in the physical volume of trade. Slow at first, this process is cumulative, and it gradually turns slow business into active business. The revival may start in a narrow field, but necessarily it spreads to other fields, because the active concerns will have more spending power, which leads them to increase their buying from other enterprises. The active concerns, moreover, employ more labor, which increases the spending power of laborers and increases the demand for many things. Increased retail demand leads to increased demand on jobbers and wholesalers, who pass it on to manufacturers, who take on more laborers, who increase their retail buying. The quickening of industry reacts on the starting point of the cycle, and the demand for many things.

"There comes, moreover, a psychological change. The 'temper of business' is not a thing which is made by men as separate individuals. Rather, it is a social product. The man who finds business in his own line expanding becomes an optimist with regard to business at large. He talks with other men. They, even though they have not felt increased orders for their own goods, begin to be influenced by his optimism. The process is partly rational and partly non-rational. The mere fact that men find their neighbors more cheerful influences them unconsciously even in the face of facts. On the other hand, the man who has been delaying an increase in his own business activity may find a valid ground for taking positive action if he finds increasing confidence among those about him. The temper of business, an intangible and psychological thing, is none the less one of the most fundamental realities with which business men must reckon.

MONEY AND EXCHANGE

Foreign quotations on June 1 are as follows:

Sterling, dollar:	Cable	3.92
	Demand	3.94
France, cents:	Demand	7.79
	Demand	7.80
Lire, cents:	Demand	5.97
Marks, cents:	Demand	2.73

Eastern Metal Market

New York, May 26.

Business is exceedingly light in all the markets and prices are mostly lower. The railroad situation is responsible for the former and the decline in the London markets is a large factor in certain metals.

Copper demand is light but prices are firm.

Buying of tin for future shipment has declined decidedly and prices are lower.

The lead market shows little change.

There is still no life to the zinc market and prices have again receded.

Antimony has also declined.

IRON AND STEEL

Improvement in freight movements has been slower than expected. Fuel continues at the moment to be the first consideration of both mill and consumer, and naturally every effort is being made to move raw and manufactured materials, says 'The Iron Age'.

Of the leading producing centres greatest relief from the traffic congestion appears in the Pittsburgh district. The scattering of railroad workers to lucrative employment, in some cases with municipalities, is checking rapid resumption of the railroads and the now heavy use of the motor-truck for relatively short hauls promises to remain more general in the future.

Uncertain deliveries have chilled buying and the few cancellations reported are not indicative of any cessation in demand. Steel plates and structural material are easier. Prices in general are not only well sustained, but several advances have been made. Consumers are bidding against each other for coke and fully \$2 more per ton has been obtained for both the furnace and foundry product.

COPPER

The most interesting piece of news in this market is the fact that refinery operations have dwindled to considerably less than 50% of capacity as a direct result of the transportation situation. In some cases certain plants have had to shut down and then been able to operate again for a short period. Buying is only moderate from domestic consumers but foreign demand is still good. There is no incentive to buy when shipments are so uncertain, particularly from the East where railroad congestion is perhaps the worst and where most of the copper is refined. Of the refined output for the first five months of the year it is stated that about 43% went abroad or 265,000,000 lb., of which Japan took at least one-fourth. Leading producers continue to quote electrolytic copper at 19c. for early delivery, with 19.25 to 19.50c. asked for July-August shipment. In the outside market there are isolated transactions as low as 18.12½ to 18.25c. by dealers or speculators.

TIN

There has been a decided cessation in the buying of future-shipment Straits tin which has characterized the past three weeks. In the week up to Monday about 350 tons was sold but the demand has about ceased. Consumers seem to be afraid to enter the market, due largely to a further slump in London, and they are waiting to see whether the market has touched bottom over there. On Thursday and Friday last week one seller sold a fair amount but there is no extended demand. Banca tin was sold on Friday last at 18.87½c. for 30-day shipment from London. In the past week future-shipment Straits has sold from 51 to 53.75c., depending on the position, and 99% tin has sold for 49 to 19.75c. for August delivery. Monday of this week was a holiday in London and consequently the market here was stagnant. Spot Straits tin in New York has hovered around

53c. the past week, but yesterday fell to 51c., due to a decline of 16 pence per ton in the London price, which yesterday was £289 per ton. A week ago it was £302 per ton. Arrivals thus far this month have been 6180 tons with the quantity afloat reported as 1340 tons. An interesting item is the reported arrival of 3880 tons of tin ore thus far this month.

LEAD

The only interesting factor in this market is the scarcity of spot and prompt-shipment lead in the New York market. As high as 9.37½c. has been paid for spot and 8.75c. for prompt shipment from the West. For later nearby deliveries 8.50c., New York, has been realized. The market is quiet but steady. We quote the outside market at 8.15c., St. Louis, and 8.50c., New York, with that of the leading interest unchanged at 8.25c., St. Louis, and 8.50c., New York.

ZINC

The market could not be more lifeless. There is almost an entire absence of interest on the part of both consumers and sellers. Only hand-to-mouth demand is being satisfied and it is difficult to get transportation. Prices have gradually declined in the week, due in part to lower values in London, but a stiffening in pounds sterling has been a steadying factor. Prime Western for delivery before August is quoted, more or less nominal, at 7.60c., St. Louis, or 7.95c., New York. Exports for March were 28,058,238 lb. against 16,159,469 lb. in March 1919. Of the March exports this year Great Britain took 18,706,833 lb., France, 6,309,990 lb., and Japan, 842,382 pounds.

ANTIMONY

The market is quiet and lower. The better grades are quoted at 9.25 to 9.50c., New York, duty paid, in wholesale lots while for other grades 9c. is asked and has been paid.

ALUMINUM

The leading producer is asking 33c. for virgin metal, 98 to 99% pure, for wholesale lots, for early delivery, with 31.50c. asked by other interests.

ORES

Tungsten: The market is still dull and featureless. Low-grade ores are quoted around \$6.75 per unit in regular concentrate. There is little prospect of any final action on the tungsten bill and until this is settled business will remain dormant.

Ferro-tungsten is quiet and unchanged at the nominal prices of 85c. to \$1.15 per lb. of tungsten in the alloy or the powder.

Molybdenum: Action in this market has been absent and prices are nominally unchanged at around 75c. per unit in regular concentrate.

Manganese: Prices for high-grade ore are unchanged at 65 to 82c. per unit, seaboard, depending on the delivery, but no new business is reported. Of the 18,970 tons imported in March, 12,200 tons came from Brazil and 1000 tons from India. Of the 151,898 tons imported for the nine months ended March 31, 1920, Brazil sent 97,396 tons; India, 12,200 tons; Cuba, 3136 tons; and Japan, 447 tons; with 38,719 tons credited to other countries.

Manganese-Iron Alloys: Still another electric plant will make ferro-manganese. A company in Alabama, which made considerable during the War, will soon start to produce again. Prices are unchanged at \$225 to \$250 for delivery before July 1, with \$200, delivered, asked for last half. While just now quiet, due to the falling off in the steel output, the market is strong. Demand for spiegeleisen, particularly from foreign sources, is good with \$75, furnace, the minimum price.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

AN IMPROVED MINE-LOCOMOTIVE

The General Electric Co. has recently developed a new mine-locomotive, which incorporates several interesting improvements over the types formerly in use. In mine work there is a considerable amount of braking to be done, owing to the numerous stops that must be made for throwing switches and coupling individual cars. The consequence is that, with the hand-brake, considerable physical effort is used by the motormen, who, if he is careless, develops the habit of stopping the locomotive by reversing the motors, thereby damaging the wheels, the motors, and the gears.

The 'braking' on the new locomotive has been made electrical to avoid this trouble. The controller is designed so that when the reverse cylinder is set at the braking position, the motors are turned into self-excited generators, the energy being absorbed in the main resistors. On a level track the motorman can bring his train to a dead stop without using the hand-brake at all, but on a grade, since there is no energy developed when the wheels have stopped turning, it is necessary to set the hand brake to hold the train. The controller is provided with a three-position indicator, 'forward', 'reverse', and 'braking' are all obtained by moving the handle in one direction. Another feature of the controller is that the points are so arranged that the motorman cannot get to parallel until he has been through series, hence he cannot get slow speed by leaving the reverse cylinder in the parallel position and running on the resistance point. This, of course, has a bad effect on the resistors, and

uses much more current than if the motors were in series.

The other features of the locomotive is its spring construction. Instead of the ordinary coil-spring, this loco-

Top View of Controller

Improved Mine-Locomotive

otive is equipped with leaf-springs of the semi-elliptic type. The springs are hung at one end of the frame, the other being connected by an equalizer bar between the two on each side. The result of the use of this bar is that, if one wheel encounters an obstruction or goes into a hole, the change in load is transmitted to the other wheels. This not only gives the locomotive better riding qualities, but decreases the tendency to de-railment. When it is de-railed, owing to the high clearance between the rail-head and the lower edge of the side frame, which is a feature of its construction, it is a comparatively simple matter to get access to the lower part of the wheel so that blocking or other de-railing devices may be put into position.

BOOKS AS TOOLS

By E. A. Goeway

The American employer, still striving to overcome the many unusual business and financial conditions which have followed in the wake of the War, is becoming more and more convinced that among the most serious features of his problems are a pronounced shortage of labor and a dearth of workers skilful to the point of high proficiency. The quantity demands of the war period no longer are maintained in many industries, and the American employer soon must face a sharp foreign competition. However, he is not losing sight of the fact that, in the long run, quality rather than quantity will stabilize 'Made in America' goods in the markets of the world. But, to do this, the domestic manufacturer must obtain employees who are thoroughly capable, that the products of the United States may equal in every way the best produced abroad. How can he obtain this much desired efficiency on the part of his employees? To this query there are many answers, but there is no question that one solution of this difficulty points straight to the magic gateway to erudition—books. Already, in line with this thought, many far-seeing manufacturers and heads of business institutions have installed in their plants special libraries of technical books for the use of their workers, as well as for reference by themselves. From such libraries the worker may obtain books giving the most minute information upon the industry in which he is employed, and such books are in demand both during the lunch hour and for quiet reading at home. This plan is not a tentative scheme, but an established fact, and in such places as it has been followed it has met with the greatest favor on the part of both the employer and the worker. Among the great commercial and business institutions which have found that the installation of a special library of technical books was a wise step, might be mentioned: Marshall Field & Co., B. F. Goodrich Co., American Telephone & Telegraph Co., Studebaker Corporation, National City Bank, Winchester Repeating Arms Co., Guaranty Trust Co., National Cash Register Co., General Electric Co., Sears, Roebuck Co., and the Curtis Publishing Co.

But there still is a deplorable lack of good libraries in business houses, shops, mills, and manufacturies when the country is considered as a whole. Every employer should be brought to see the benefits to be derived from these special libraries, and an important step toward this end has been taken by the American Library Association with its peace-time enlarged program, which is being carried out with the significant slogan, 'Books for Everybody'. The enlarged program contemplates doing many things toward an even more general extension of the library service, emphasizing four outstanding features. One of these, and a very important one indeed, is with the aid of the Special Libraries Association to encourage a larger use of the technical books now in the public libraries and to urge employers of labor in factories and plants to install special libraries of technical books for the use of their employees. To assist American-

ization publishers will be asked to print standard American works, in the various foreign tongues, so that the immigrant upon arriving in this country can have this literature placed in his hands and in the language which he will understand most easily.

COMMERCIAL PARAGRAPHS

Announcement is made of the removal of the offices of the Power Plant Corporation and the Trent Process Corporation from the McGill Bdg. to 1440 Yon street N.W., Washington, D. C.

George E. Long has retired as senior vice-president of the Joseph Dixon Crucible Co. Mr. Long is 70 years old and has been in the service of the company for 43 years, during which time he has advanced from his original position as stenographer. He was largely responsible for the development of silica-graphite paint for protective purposes and for the use of graphite as a lubricant.

The Wellman-Seaver-Morgan Co., of Cleveland, has issued a series of bulletins showing some of the construction work of the company. The numbers and subjects follow: No. 41, coal and ore-handling machinery; No. 42, special cranes; No. 43, hydraulic turbines; No. 44, hoisting and mining machinery; No. 45, steel-works equipment; and No. 46, coke-oven machinery.

The Fairbanks Co., with administrative offices in New York and branch houses in all large cities, has recently issued a 256-page catalogue illustrating and describing its complete line of power-transmission appliances and elevating and conveying machinery. In addition, the catalogue contains full data as to dimensions, capacities, etc., making it a useful handbook for the man who designs or installs mechanical equipment of this nature. The book, which is attractively bound in dark green cloth, will be sent on request to executives, engineers, master mechanics, millwrights, and those concerned in procuring material described.

The sixtieth anniversary of the 'Mining and Scientific Press' emphasized the fact that for fifty-four years the business conducted by Braun-Knecht-Heimann Co. has been closely identified with the mining field, particularly the work of metallurgists and assayers. Scarcely an important mine or mill in the West but that has at some time been a customer of this firm, and most of them still are. An international reputation is enjoyed by the line of Braun laboratory machinery sold by the company and its Los Angeles affiliation, the Braun Corporation. Crushers, pulverizers, flotation machinery, cyanide supplies, cupels, glass-ware, and the scores of other supplies needed by metallurgists and assayers are carried in stock.

The Schaffer Engineering & Equipment Co., to provide for the expansion of its business and to obtain more ample plant facilities, has sold a large block of its capital stock to the Fawcus Machine Co. The Schaffer company's various lines of machinery, including poidometers, hydrators, coal injectors, and screens are well known. The rapid growth of its business necessitated better manufacturing facilities. The Fawcus Machine Co., manufacturers of gears and special types of machinery, with large plants at Pittsburgh and Ford City, Pennsylvania, will build the machinery required, and the inventive genius of J. C. Schaffer and the thorough understanding of its customers' needs of Waller Crow will be backed by the active interest which the officials of the Fawcus company will take in the Schaffer company. The officers of the Fawcus company, who will take active interest in the Schaffer organization, are A. F. Cooke who has valuable ideas in machine-shop practice; Eliot A. Keblor, prominent in financial circles and identified with iron-manufacturing companies for many years; and A. A. Alles, Jr., who has done much toward unifying and stabilizing costs in manufacturing.

T. A. RICKARD, . . . Editor

DENVER has been selected for the next meeting of the American Mining Congress. The convention will be held during the week of November 15.

PROSECUTION of paper manufacturers under the Sherman and Clayton acts has been recommended by a Senate committee that has been making an investigation into the high prices now being charged. Profiteering in paper is only one of the many consequences of the industrial disorganization due to the War, under cover of which the prices of most commodities have been raised shamelessly in order to enable manufacturers to make preposterous profits. The committee of the Senate to which reference is made has devoted its attention chiefly to news-print paper, which has risen from two cents to ten cents per pound, but a similar condition obtains in the market for book-paper, such as is used by magazines and other periodicals, the publishers of which have to pay as much as 20 cents for paper that cost 4 cents four or five years ago. Whether the increase is legitimate or not is answered by the fact that the manufacturers are making money hand over fist, and obviously are in collusion.

THE sailing of the steamship 'Victoria' on June 4 from Seattle for the Seward peninsula and Nome recalls the occasion, exactly 20 years ago, when the rush started that made a tented city of 30,000 assorted miners and adventurers, crooks and tenderfeet on the shore of Bering Sea during the summer of 1900. The underwriters will not permit an insured vessel to enter the ice-infested waters until after June 8, so that each year the first boat starts for the north early in that month. The last ship 'out' leaves Nome in October; during the long winter the only communication is overland by dog-team over hundreds of miles of desolate snow and ice, by way of Fairbanks. The 'Victoria' has been making the journey regularly since 1908, but this year scarcely a quarter of her cargo is destined for the town made famous by its gold-laden beach-sand from which \$5,000,000 was won with no more elaborate machinery than the 'rocker' and the 'long-tom'. Those who came out on the last boat in October 1899 carried with them enough 'dust' to substantiate their reports of the richness of the deposits on Anvil, Dexter, Dry, and other creeks, and on the beach itself. The news spread so that twenty years ago many an old bulk was rehabilitated to take the

thousands of gold seekers, who thronged the wharves of Seattle and San Francisco, intent upon being the first to reach the new diggings and an easy fortune. Many became rich, more suffered bitter disillusion. Now Nome is an orderly town on the frontier; it is a meeting place for the civilization of the peoples of the temperate zone and the simple barbarism of the natives within the Arctic circle.

DURING the past week the representatives of the national engineering organizations have been in conference at New York under the leadership of Engineering Council. If the American Association of Engineers can abate some of its claims, it is probable that a real union of engineering societies, for the general benefit of the profession, may be effected. Incidentally, we note with pleasure that the 'A. A. E.', as it is called for short, on the occasion of its recent convention at St. Louis, endorsed the following statement issued by the directors of that organization: "We believe in organized representation for the correction of wrong, the advancement of the engineering profession and service to the public, but are opposed to methods inconsistent with the dignity of the profession and which would lessen public confidence in engineers. The American Association of Engineers, recognizing the many fundamental differences between the principles of the trade-union and an organization of professional men, expresses the opinion that an engineer cannot subscribe to the tenets of both." The resolution recommended the expulsion from the Association of engineers who advocate strikes or similar methods of securing their ends. This is a move in the right direction, if it mean that engineers as a body will use their best effort to reconcile disagreements by conciliation, arbitration, and fair adjustment.

OIL THIEVES is the title of an article issued by the petroleum section of the U. S. Bureau of Mines. One might suppose that it discussed the theft of oil, but instead it describes the manner of taking samples of oil at intervals beneath the surface of the liquid in a tank. The writer calls it a "fluid", which is not precise, because 'fluids' include gases as well as liquids. However, that is by the way. The instrument used for the purpose of this sampling is called an 'oil-thief' and the method is known as 'thieving'. Consequently the article is full of such phrases as these: "Thieves of all types

have their good points". "The purpose of thieving oil is to obtain, etc.". "The thief has an apparently insignificant part in the handling of oil". We submit that the use of a common word in a technical sense is objectionable, because it causes a repeated derailment of thought and a confusion of ideas entirely prejudicial to the purpose of the writing, which is to convey information to the reader as effectively as possible, and, we may add, as pleasantly as a technical subject will permit. We shall be told, of course, that 'oil-thief' is a well-established term in the oil industry and that we are running our head against a brick wall of custom. That may be. We refer to it now merely as an example of the manner in which technicians allow Tom, Dick, and Harry to supply them with terms that ought to be significant and precise, but are nothing of the kind. Another example is 'vegetable'. People talk about 'vegetable oil', and 'vegetable kingdom', thereby awakening the idea of cabbages and peas, just as if the adjective 'vegetal' did not exist. We might as well talk of the 'beast kingdom' instead of the 'animal kingdom'. In these matters technical men are too lazy; indeed, they are unscientific because they use an instrument of precision, their language, carelessly.

SUNDRY interesting conclusions regarding the nature of the damage done to farms by smoke from lead and copper smelters appear in the recent findings of Judge Johnson, of the U. S. District Court at Salt Lake City. Twenty years ago it was realized that crops suffered to some extent from the effects of smoke. The result was a series of lawsuits, some of which were tried and many of which were merely threatened and settled out of court. Some of the farmers derived more profit from their 'blighted' crops than they might have done from their harvests alone, had the smelters not become a source of revenue to them. The idea then developed that the fume was a menace to the health of cows, pigs, and horses; and even the corrosion of barbed-wire fences was attributed in some instances to the smelter-smoke. In order to determine just how much harm the smoke really did, and to ascertain just what constituents were injurious, the United States Smelting company at Midvale and the American Smelting & Refining Company near its Murray plant started experimental farms in charge of trained investigators, who undertook to solve these problems in a scientific way. The introduction of bag-houses, and later of electrical precipitation devices, followed, and so successfully have they been developed that practically all the solid particles in the smelter-smoke can now be removed before it leaves the stack; so that whatever damage is done must be accounted solely to the gaseous constituents. In the opinion handed down by Judge Johnson, in the case in which the two companies are co-defendants, the findings are based largely on definite proof resulting from the experiments conducted on the company farms. He finds that there is no "invisible injury" to vegetal tissue, but that plants must be bleached or burned perceptibly, presumably by sul-

phuric acid produced from sulphur di-oxide gas, before they are harmed; that there is no injury to screen or wire fences resulting from the operation of these smelters; that there is no injury whatever to animal life; and that as regards the health of human beings, the only possible harm is that which may arise from mental disorders induced by imaginary worry. It would seem that so-called Christian Science ought to be an effective preventive for the last trouble. The only possible ground for just complaint appears to be damage to plants; this can be minimized by sufficiently diluting the sulphur di-oxide with air, and the obvious way to accomplish this is to build high stacks; if the gases are discharged into the atmosphere at a point far enough above the ground, diffusion and dissipation by air currents will render them so dilute as to be innocuous by the time they reach the earth. The outcome of the suit is a victory for scientific research. The farmers themselves, if they want to be reasonable, can have the facts proved to them by actual demonstration.

E. Gylbon Spilsbury

On another page we publish a formal obituary of E. Gylbon Spilsbury, and we regret deeply the occasion for it. He lived to a good old age and enjoyed a career unusually rich in variety of experience; he was successful in his profession and he was elected to positions of honor; but he achieved much more than that; he made friends and held them. Among the men of the passing generation, none showed a wider or more generous sympathy with those about him, or a more instant willingness to be helpful to those less fortunate than himself. Above all, he had the lovely trait of being interested in other people and in doings outside his personal participation; he kept himself young in spirit, long after he was old in body, by this keen interest in all that was happening in the world about him. Many men now seniors themselves will remember how kind he was to them when they were callow youths and will join with us in this tribute to his memory. He leaves three worthy sons; to them the name of their father should be a stimulus to good work and right thinking until they in turn transmit the Spilsbury tradition to their sons.

American Mining Engineers Abroad

Various statements have appeared in the Hearst papers charging the British government with orders in council and other regulations prejudicial to the management of enterprises in the British dominions by Americans. On June 5 it was announced at Washington: "Authoritative information has revealed that the recent order in council requiring firms under British registry in China to be managed entirely by British subjects was aimed at certain companies which have abused the privilege for purposes such as smuggling opium. It is declared that the order was not directed against foreign interests as such, and least of all against American interests." It

has been stated that American mining engineers have found it difficult to remain as managers of British-owned mines in foreign countries and even that Mr. Hoover was compelled to sell his shares in the Burma Mines, Ltd., on account of his nationality. This last statement we know to be without foundation. As to the larger assertion, of unfriendly discrimination against American engineers, we have taken pains to write to American and British mining engineers in London for precise information, and we are glad to say that the rumors are said to be untrue. During the War, of course, there were suspicions and inquiries directed against Germans and Austrians who under cover of American citizenship were acting as agents for the enemy countries, and our own experience of the misuse of naturalization in this country will suffice to indicate how necessary the British may have found it to be particular in regard to the freedom of action allowed to suspected persons. During recent years a number of American mining engineers formerly resident in England have returned home, but this is due to causes fairly obvious, among which we may mention the diminution in British mining enterprise, due to the restrictions imposed by the British Treasury on the raising of fresh capital, the practical cessation of mining operations in Siberia, the high income and excess-profit taxes, and the call that the United States made to its own citizens as soon as it entered the War. Since the Armistice there has been a plague of recrimination and jealousy between the peoples that were allied against the common enemy, and sundry newspapers on both sides of the Atlantic have given vent to their spleen, playing into the hands of the pro-German and Sinn Féin factions, and of the more numerous persons disgusted by high prices and the shameless profiteering that have killed the generous emotions evoked by the stress of conflict. Moreover, in Europe, there is a feeling, which, to be candid, we must recognize, that the United States has not lived up to the fine humanitarian spirit expressed in the days of extreme crisis and that the withdrawal from the League of Nations is an action not in accord with the confident expectations engendered by American participation in bringing the War to an end. That is a subject for controversy, unfortunately, and we mention it only to make the record complete and to explain the disappointment that prevails in London and Paris. It has not had any direct effect upon the pleasant relations subsisting between the English-speaking members of the mining profession, and we hope that even its indirect effects will pass in due time, when our domestic political issues have been settled by the election of a new President and a Congress instructed to act for the Nation in the further readjustment of the world's affairs. We, of course, are jealous in behalf of our profession, wherever it may be called upon to exercise its talent in the exploitation of mines and the management of mining enterprises abroad; we would regret, and resent, any discrimination against the American mining engineer whether in Mexico or South Africa, but we have surer reason to resent the

campaign of misrepresentation conducted by the gutter press, such as Hearst's in San Francisco or Bottomley's in London. If any American mining engineer has cause to complain of unfair treatment under any foreign flag, we invite him to state his case in our columns, and we promise to draw the attention of the proper authorities to the matter, so that it may be investigated in due course. Many of our American mining engineers are members of the Institution of Mining and Metallurgy in London; the council of that engineering society has never failed to show goodwill to Americans as such; indeed it elected an American as its president twice; we feel sure, although having no authority whatever to say so, that the Institution would second any efforts made from this side to prevent discrimination against any properly qualified American engineer in the exercise of his professional duties or the advancement of his career under the British flag, just as surely as the American Institute of Mining and Metallurgical Engineers would endeavor to prevent any similar unfairness to a British engineer performing his proper function under the American flag. Let Hearst and Bottomley rage; the solidarity of our profession, within the bounds of genuine patriotism, will not be endangered so long as we are frank to one another and true to the tradition of our calling, which is to convert the resources of Nature to the use and benefit of mankind by the application of technical science and organized industry.

Prospects in Mexico

The public interested in mining is watching with close attention the course of events in Mexico. To a large group of mining men the country south of the Rio Grande is the most attractive mineral region in the world; to them the call of Mexico is as insistent as that of Alaska to the 'sourdough' or of the Transvaal to the Afrikaner. We sympathize with that attraction toward the land of the Aztecs, for Mexico unquestionably is a mining region of remarkable character and unrealized wealth. When will it be re-opened to peaceful industry, more particularly the working of mines by American operators? First we shall glance at the report of the sub-committee selected by the Foreign Relations Committee of the Senate. This report was issued on May 31 and is the joint product of Senators Albert S. Fall, Marcus A. Smith, and Frank B. Brandegee, representing the States of New Mexico, Arizona, and Connecticut respectively. The report embodies the results of a thorough investigation; it is likewise thorough in its recommendations, which, briefly, are that recognition of any new Mexican government be withheld until it shows evident marks of stability and "the disposition to comply with the rules of international comity". Recognition is to be contingent further upon the assurance of protection to American citizens and the payment of indemnities for damages done to them in Mexico. As a matter of record it is stated that 461 Americans have been killed in Mexico and 126 more at the border, during the recent years of

misrule. Claims for damages amount in all to \$505,002.-434. Restrictions and prohibitions against the ownership of property or the doing of lawful business by Americans in Mexico are not to be endured and must be cancelled. If the Mexican government should continue to discriminate against our citizens or subject them to further indignities, it would be the policy of the United States not only to refuse recognition to the Mexican government but to send a police force to impose order and to keep open the lines of communication between the city of Mexico and every seaport of the country. If, on the contrary, the Mexican government should prove friendly and should manifest its ability to restore order, then it is to be the policy of the United States to accord to Mexico not only its "moral support, but financial aid without stint in so far as same is necessary for the refunding of all Mexican bonds, including the external as well as the internal debt, with additional funds in sufficient amounts to rehabilitate all the Mexican railroads and to maintain same, and also sufficient amounts to enable the recognized government to re-establish, organize, and thoroughly equip a purely national army not belonging to any particular chief, chieftain, or general, but operating under the national government, which shall immediately proceed to disarm all other armed forces or individuals in the republic". The report closes by asserting it to be the national purpose to protect our citizens in Mexico, so that they can go about their business in safety. It is high time that this pronouncement were made; we hope that the report will lead to administrative action and that the fundamental idea of safeguarding our nationals in their peaceful and lawful occupations anywhere will be endorsed by the Congress and the President. To the mining profession such a declaration of policy would be of vital importance, for without it the American engineer is grievously handicapped in Mexico and elsewhere, as compared with the nationals of other countries whose governments show themselves more solicitous in this regard.

Senator Fall's report can hardly be called diplomatic; parts of it are couched in terms that might be deemed offensive to our friends in Mexico, as for example, the direct threat to send a police force to open and maintain the principal lines of communication, but we anticipate that the Secretary of State, should he act upon the report, will soften the language so as not to hurt what the President has called "the proud punctilio" of the señores below the Rio Grande. Certainly it is time to speak frankly to our southern neighbor if we are to understand each other. No reason should exist for relations much less friendly with Mexico than with Canada; southward, as northward, the American mining man ought to be assured of the protection not only of his own government but also that of the country in which he is conducting his lawful business, to the mutual benefit of the individual and the country of his sojourn.

General De la Huerta, the President *ad interim*, and General Obregon, who appears most likely to be chosen as President in the forthcoming election, three months

hence, have expressed sentiments of good-will toward the United States and its people. The pro-German and pro-Japanese Carranza has gone the way of unpopular Mexican presidents; we are warranted in anticipating a more friendly policy from his successors. In order that there may not be too many of them in too short a time it is necessary that the plague of generals be lifted from Mexico, that the pseudo-militaristic regime be broken decisively, and that the civilian element be given control of the administration. A group of young men, posing as soldiers, but in reality only grafters, has dominated Mexican politics during recent years, and even during the days of Diaz. They have looted the treasury and victimized the people; and nobody knows it better than General Obregon. It is to his interest to stamp out the plague, which otherwise will menace his own position as President. Under Carranza's regime two-thirds of the Federal appropriations went to the Department of War and Marine, which means that they went to the Army. It was an army that was unable to prevent brigandage or even to quell sporadic revolution because it existed largely on paper; the 120 millions of pesos allotted to it went largely as loot to officials, chiefly a group of about fifty generals and their staffs, most of whom have been living riotously on their spoils. Even Diaz, when at the last his autocracy was menaced, found that the 100,000 soldiers for whom he had been paying were a fiction, and that he could put only 14,000 in the field. From the sum allotted to each commander of troops for rations to his men and for fodder to his horses, a major portion is withheld—that is, stolen—because the commander puts the horses to graze on private land and contents himself with a nominal fraction of the men supposed to be under his orders. Each general has a few retainers of whom he takes good care and on whom he can depend whenever he changes his support from one side to another, so that in the end the country is dominated by a group of bandits in Federal uniform. The military feature is subordinated to a vulgar graft that is hardly masked by the gaudy veil of politics. Meanwhile the schools and railways have been deprived of the funds necessary to maintain them, so that education and industry are starved. So are the people as a whole; for what inducement is there to grow corn or to breed cattle when both products may be seized without compunction by a 'general', claiming to represent Federal authority, but actually an irresponsible young thief in a gaudy uniform. General Obregon knows all this well enough and he realizes that unless he breaks the system that holds Mexico by the throat his own government will be imperilled at the start and his efforts to restore the country to peace and quiet will be defeated. There is much for him to do; he must retire the 'generals' and organize an effective police force after the style of the old *rurales* of Diaz. After that he will have to stamp out brigandage whether it be of the cut-throat type, like Villa, or a polite *revoltoso*, like Pelaez. We wish him luck, for we also have felt the charm of Mexico and of its people, and would like to go to Mexico again.

DISCUSSION

The Case Oil-Fired Assay-Furnace

The Editor:

Sir—The defects cited by F. Borzynski in his article in your issue of May 15 on the operation of the Case oil-fired assay-furnace would deter anyone from using it.

Being, at an earlier date of their usage, an operator of such a furnace, I can vouch for their high efficiency under any stress of importance, as well as in times of rush, and especially on good check-work on silver cupellation.

The effects of reducing gases or flame were never noted. Much depends on burner adjustment in order to secure an economical and perfect degree of combustion. For this the low-pressure air-flame cannot be rivaled, allowing, as it does, the flame to envelop itself around and over the top of the muffle, producing an all-round even temperature throughout the entire length of muffle.

One cause of trouble in preventing burner efficiency is due to the drying out of oil at the nozzle, which obstructs the passage of air, causing imperfect combustion. A daily rub-down of the burner with kerosene-oil will prevent this.

The furnaces adapted for use with hood-chimney I would recommend as requiring no damper adjustment whatever.

McGill, Nevada, May 25.

Indicators

The Editor:

Sir—In the article (No. V) on 'The Bunker Hill Enterprise', appearing in your issue of February 21, page 262, occurs the following:

"Under this seam [the gouge] is a white, creamy, or buff band, ranging from a few inches to a foot or more in thickness, of crushed quartzite which is so finely powdered as to form what is usually termed sugar quartz. The white band contrasts strikingly with the black clay seam."

The peculiarity described resembles what miners have noticed in many other mines, and what they call an 'indicator'. The writer of the above description does not give any explanation of the formation of this peculiar seam of white material, nor have I seen any explanation of similar occurrences anywhere. Can any of your readers give an adequate explanation of these phenomena and how they came to be so?

In our mine here the orebodies are accompanied by such a seam, which is called by the men 'bleached

shale'. The country consists of tuffaceous shale and slate, and is often quite black near the ore. The bleached shale could be described exactly by the words used in the above quotation, except that it is compact and not crushed into powder, and it is not quartz, but apparently of the same composition as the black shale. Where the lode and country are crushed and contorted, the bleached shale is also. This bleached shale is associated invariably with the ore, and is found extending beyond the ore accompanying the fissure and gouge, where there is no ore, but there is never ore without the bleached shale seam. It is regarded by the miners as a sure sign that they are in an ore-channel.

I cannot form any theory about these peculiarities; my chemical knowledge is quite at sea on the subject. I notice the confident explanations so often given of exactly where the ore comes from (I have just read one, dismissed in a few convincing lines!), that I feel sure some of our younger men can tell us, what must be very simple, if we only knew.

Technical Writing

The Editor:

Sir—I was interested in A. T. Parsons' review of your new book, 'Technical Writing', in your issue of May 8, because I had just written a review of the same book for the 'Engineering News-Record' (issue of May 20). Mr. Parsons recommends that engineers should obtain a copy of the book and act upon its suggestions. Certainly the book is well suited for helping engineers to improve their English. However, I have noticed one curious consideration in teaching technical writing to engineers, both graduate and undergraduate: one type of engineer resents criticism of his English in much the same spirit that he resents criticism of his looks or his family. Even when a man of this type joins a class to learn English, he wants to be praised rather than be shown his defects. On the other hand, there is an increasing number of engineers that realize the need for devoting serious thought to improving their English. In some teaching that I have been doing at the Western Electric Company, where I had a class of engineers averaging 35 years old, I found research engineers and heads of departments keener about learning English than I ever expect undergraduates to be.

The Theory of the Centrifugal Fan

By WALTER S. WEEKS

*INTRODUCTION. The performance of centrifugal fans is one of the most elusive subjects that confronts the mining engineer. It is my object in this article not to discuss the intricate design of fans, but to so explain their action that the operator may be able to visualize what goes on in the fan and so be able to predict or explain the results of particular applications.

Fig. 1 shows a section and front view of a simple fan. The air enters at the inlet on the side, and flows out radially through the blades until it strikes the fan-casing. It then follows the casing to the discharge.

A centrifugal fan is an air-pump. It takes air at one pressure and raises it to a higher pressure. Its use is to produce a difference in pressure between inlet and outlet. If we attach the inlet of the fan to the mine, the fan will take air at a static pressure below that of the atmosphere, because in order to make the air flow into the mine at the other opening, as it will in this case, the fan must establish an incomplete vacuum at its inlet. It will pump this air up to atmospheric pressure. Such a fan is called an exhaust-fan. If we attach the discharge of the fan to the mine, the fan will take air at atmospheric pressure and pump it up to a pressure above that of the atmosphere. Such a fan is called a pressure-fan. In this article I shall deal entirely with pressure-fans unless otherwise stated.

CENTRIFUGAL PRESSURE. Let us now see how the fan produces its pressure.

Suppose we whirl an apple around on a string with a as a centre. See Fig. 2. How much does the apple pull out on the string?

Let W = the weight of the apple.

r = the distance from a to the centre of the apple.

U = the linear velocity of the apple through the air in feet per second.

F = the pull in pounds on the string.

g = the acceleration due to gravity.

$$F = \frac{W U^2}{g r}$$

This pull F is called the centrifugal force.

*This is the second of a series of articles by Professor Weeks on the ventilation of mines. In the first article 'The Friction of Ventilating Currents', which appeared in the issue of August 24, two typographical errors occurred. On page 609 in the derivation of the formula the equation read

$$\frac{Q_1}{\sqrt{K \cdot S_1}} = \frac{Q_1 + Q_2}{\sqrt{\frac{A_1}{K \cdot S_1}}} + \sqrt{\frac{A_2}{K \cdot S_2}}$$

and the equation at the bottom of the same column should read.

$$K = \frac{p \cdot A}{S \cdot V}$$

Now let us suppose we have a pipe full of air as in Fig. 3. On the end of the pipe is a rod ab . The rod and pipe are whirled about a as a centre. The outside end of the pipe is closed. If we divide the air in the pipe into sections as shown, each section is like the apple. The force that it exerts on the one ahead of it may be calculated by the formula for centrifugal force. The farther away from the centre of rotation the section is, the harder it pushes. This is because the velocity increases as we go out from the centre. By calculus, we are able to obtain the sum of all the forces that the sections exert. We find that the pressure in pounds per square foot that the tube of air produces at the outside end is $w \frac{U_2^2 - U_1^2}{2g}$ where w is the weight per cubic foot of the air in the tube, U_2 is the linear velocity of the outside end of the pipe in feet per second, and U_1 is the linear velocity of the inside end. This calculation is based upon the assumption that all the air in the pipe is of the same density.

We may imagine the spaces between the blades to be made up of like tubes, so the centrifugal pressure produced by a fan is $\frac{w (U_2^2 - U_1^2)}{2g}$

where U_2 is the linear velocity of the tip of the blade and U_1 is the linear velocity of the heel of the blade.

The question may be brought up, is not the air at the outside end of the pipe more compressed than the air at the inside end, and hence of greater density? Therefore will the sections on the outside not press harder than the sections on the inside? The sections near the outside are heavier, but in ordinary practice the pressure that a mine-fan exerts is usually not over 5 in. of water, so the difference in pressure between the inlet and outlet is so little that the change in density may be neglected.

VELOCITY-HEAD. Besides the centrifugal force, we have another source of pressure, namely, the velocity-head in the air as it leaves the fan-blade. If we can slow down the air after it leaves the blade we can change this velocity-head into pressure-head. The gradual enlargement of the fan-housing in the form of a scroll is for the purpose of converting velocity-head into pressure-head. We should leave only enough velocity in the air to carry it away from the fan and into the mine at the desired speed.

This brings us to the question of velocity-head in the air. If a tank of water is h feet deep, and we punch a hole in the bottom of the tank, the water will flow out with a velocity of v ft. per second where $v = \sqrt{2gh}$, h being the head of water in feet.

Whence $h = \frac{v^2}{2g}$ is called the velocity-head. It is the head in feet that will produce a velocity v . Now, if

the density of the liquid is w lb. per cubic foot, the pressure on the bottom of the tank is wh , or the pressure that can make the water flow out of an orifice with a velocity of v ft. per sec. is $\frac{wx^2}{2g}$ lb. per square foot.

In the case of the tank, we changed pressure head into velocity-head. If we conduct the liquid with a velocity of v into an expanding cone so that the velocity is gradually decreased, the velocity-head will gradually change back into pressure-head.

It is useful to know what velocity of air in feet per minute has a velocity-head equivalent to one inch of water.

If we take 62.31 as a standard weight per cubic foot for water

$$\frac{wx^2}{2g} = H \text{ 62.31. } H = \text{feet of water.}$$

$$\frac{wx^2}{2g} = \frac{i}{12} \times 62.31. \quad i = \text{inches of water.}$$

If we take w as the weight of one cubic foot of dry air at 70°F. and at a pressure equivalent to 29.92 in. of mercury

$$v = \sqrt{\frac{2g \times i \times 62.31}{12 \times 0.07495}} = \text{velocity in feet per second.}$$

Give i the value 1 and multiply by 60.

$$V = 60 \sqrt{\frac{64.32 \times 1 \times 62.31}{12 \times 0.07495}} = \text{velocity in feet per minute.}$$

$V = 4005$ ft. per minute.

This means that a current of air of this density flowing with a velocity of 4005 ft. per minute, if slowed down gradually to 0, would produce a pressure equivalent to that of one inch of water.

Velocity-head varies as the square of the velocity, so to determine the water gauge equivalent to x feet per minute we must multiply 1 by $\frac{x^2}{(4005)^2}$.

For ordinary calculations the round number 4000 may be used.

To return to the fan: ab (Fig. 4) represents a straight blade rotating about O . Air flows from the centre of the fan to the outside. If we stood on a fan-blade the air would pass us with a relative velocity of V . The tip of the blade is moving with a velocity U , so when the air leaves the blade it is moving with an absolute velocity of v ft. per second. As we let more air enter the fan, V increases, so v also increases, but its direction changes.

The velocity-head in the air as it leaves the blade is $\frac{v^2}{2g}$. If we can slow this down gradually we can change it into pressure-head. If the air left the blade with a velocity of 4005 ft. per minute and we were able to convert half the velocity-head into pressure-head we should obtain a pressure equivalent to that of half an inch of water. In the present example, a lot of head will be lost in shock when the air hits the casing.

We can control the amount of velocity-head with which we must deal by changing the curvature of the blades. See Fig. 5. In this figure we have a blade curved forward. V and U are the same as before, but v is seen to be increased. Moreover the air is leaving the blade in a

direction such that it will meet the casing without shock. The more air that flows through the fan the greater v becomes.

If we wished to make r very small, we could turn the blade backward. This is done in the case of the centrifugal pump, because with water it is difficult to change the velocity-head into pressure-head inside the pump.

ACTION OF THE FAN. So we have two sources of pressure: centrifugal force and velocity-head.

When a straight-blade fan is closed tight the pressure that we would expect to be developed is that of centrifugal force alone, because no air is flowing. We do, however, have the transient effect of the impact of the churning air against the outlet-gate. This impact-pressure disappears when the gate is opened.

As we let air into the fan, the centrifugal head remains practically the same and we have added to it such pressure as we may recover from the velocity-head in the air. When the gate is opened a little, the velocity of the air as it leaves the blade is nearly equal to the speed of the tip of the blade but very little is recovered on account of the turbulent eddies in the fan. As more air is admitted, the recovery becomes more marked. At all times enough velocity must be left in the air to carry it out of the fan at the desired speed.

I shall use the term 'over-all pressure' to signify the centrifugal pressure plus the amount of pressure we recover from the moving air in the fan-scroll.

When air is first admitted to a straight-blade or forward-curved-blade fan the over-all pressure rises for a time. Later, as more air is admitted, the velocity of the air leaving the tip increases, but we do not know how much of this is recovered, so we cannot tell whether the over-all pressure is increasing or decreasing.

The old long-blade coal-mine fan obtained its pressure primarily from centrifugal force. The blades were straight or curved backward. The type of fan found mostly about metal mines is the newer multiblade fan. Fig. 6 is a fan-wheel of this type. The blades are short and curved forward. These fans depend largely for their pressure not upon centrifugal force but upon giving the air a high velocity and then converting the velocity-head into pressure-head. To develop great centrifugal pressure, long blades are necessary, as we know from our study of the air in the revolving pipe.

From the energy equation of the fan we may deduce that the over-all pressure, as we have defined it, is equal to the static pressure produced at the outlet of the fan plus the friction of the air in flowing through the fan plus the velocity-head at the inlet. Now the velocity-head at the outlet of the fan is practically the same as the velocity-head at the inlet. So we may say that the over-all pressure overcomes friction in the fan, supplies the pressure to balance the mine resistance, and supplies the velocity to carry the air into the mine. This over-all pressure multiplied by the quantity of air delivered per minute is the power consumed by the fan in accomplishing the three objects stated. The actual power required to run the fan is a great deal more than this because

power is consumed in eddies, friction of the rotating air against the sides, and in bearing friction.

THE CHARACTERISTIC CURVE. To ascertain just how much pressure will be available for overcoming the mine resistance we may plot a pressure-volume characteristic curve of the fan. The data for such a curve are obtained as follows: Connect a few lengths of pipe to the discharge and place a gate at the end. Run the fan at constant speed. Take the pressure with a water-gauge at the fan-outlet. Start with the gate closed and record the pres-

sure. Now as we admit air to the fan, the air flows through the discharge, the impact-pressure is partly destroyed, and the conversion of velocity-head into pressure-head begins to take place. Friction of the air through the fan increases also. The increase in velocity-head recovered overcomes the increase in friction for a while, and the curve rises. Friction soon gets the better, however, and the curve begins to fall, and continues to fall until the gate is wide open. So in the case of a fan with long straight or backward curved blades we may

Rotating
Curved Blade

sure. Open the gate a little, record the pressure, and measure the air flowing. Continue until the gate is wide open. Now, if we plot static pressure in inches of water against quantity of air flowing, we have what is called a pressure-volume characteristic curve. Fig. 7, A is such a curve for a straight-blade fan. For any given amount of air the pressure at which we may obtain that air is fixed and may be read from the curve.

If, as air is admitted to the fan, the over-all pressure increases faster than the friction in the fan plus velocity-pressure in the air leaving the fan, the characteristic rises. If the over-all pressure does not increase as fast as those other terms, the characteristic falls.

Let us study the curve of the straight blade fan, A (Fig. 7). When the fan is shut tight, the pressure is produced by the centrifugal force of the revolving air and by im-

say that most of the curve is falling so that as we admit more air to the fan the pressure at which we can obtain the air decreases.

Fig. 8 is the characteristic of a multiblade fan. It is difficult to explain fully the antics of the fan at the beginning of the curve. The multiblade fan has short blades, but when the fan is closed tight all the air in the casing is rotating, so we might expect a centrifugal head of $\frac{U_2^2}{2g}$ where U_2 is the speed of the blade-tip. But we sometimes find that the pressure under these conditions is more than twice this amount.

The great difference between the head produced by the multiblade fan and the straight-blade fan under the condition of no-air delivery must be due to velocity conversions from eddies and from greater impact.

When we let the air begin to flow through the fan the normal current is established through the fan and the churning and short circuiting are diminished. This causes a drop in pressure, until the proper conversion of velocity-head into pressure-head becomes effective, and the curve rises. Later, as in the case of the other fan, friction wins, and the curve falls until the gate is wide open.

ELECTRICAL ANALOGY. To those who understand electricity, I may perhaps make clear the general theory of the fan by using as an analogy a compound-wound direct-current generator with separately-excited shunt-fields. The series-coils are of course in series with the armature. This analogy, though not perfect, is close enough to be serviceable.

The total voltage produced by the generator corresponds to the over-all pressure of the fan. The IR drop in the generator corresponds to the drop in pressure in the fan. The terminal voltage of the generator corresponds to the water-gauge at the fan-outlet. The voltage produced by the shunt-coils is constant and corresponds to the centrifugal pressure produced by the fan. The voltage produced by the series-coils corresponds to the velocity-pressure recovered in the fan-housing. The current corresponds to the air. The more current that flows, the bigger the voltage from the series-coils and the bigger the total voltage. The generator characteristic curve corresponding to the pressure-volume curve of the fan is terminal volts against amperes. As we allow current to flow the total voltage increases and the IR drop through the generator also increases. If the gain in voltage due to the series-coils as current is increased is greater than the IR drop in the generator, the terminal voltage rises and the characteristic rises. If the gain in voltage is less than the IR drop, the curve falls.

FAN-RATING. Let us now look back at the curve shown in Fig. 7. We see that there are an infinite number of combinations of pressure and corresponding volume. What shall we call the capacity of this fan at the speed for which the curve is plotted? Laying aside for the moment the consideration of 'commercial efficiency', we would naturally say that this fan should be used at the point on the characteristic curve where it will give the highest mechanical efficiency. So if we plot a mechanical-efficiency curve on the same chart with the pressure-volume curve we may see at a glance at what combination of pressure and volume the fan should be used to give the highest mechanical efficiency. From the chart we see that this fan should be rated at 22,000 cu. ft. of air and 1.82 in. of water when running at the speed at which the chart was plotted. The method of obtaining the efficiency curve I shall discuss under fan-testing. If any element in the design of a fan is changed the characteristic changes, so in order to predict the action of a fan under a given set of conditions it is necessary for the engineer to obtain the characteristic from the maker.

The power to run a fan at a given speed constantly increases as air is admitted to the fan. When the fan is taking air at atmospheric pressure and discharging it at

atmospheric pressure, the entire over-all head is used up in fan friction and velocity. When this condition maintains, the fan has the greatest load that can be put upon it. I once asked a mine foreman what would happen if he left open the door between the inlet and discharge openings of an underground fan. He replied that the fan would race like an automobile motor when the clutch was suddenly thrown out. As a matter of fact, it would have put the maximum load on the fan and the motor might have burned out.

FAN LAWS. There are certain useful relations that exist between the speed of the fan and the pressure, quantity, and power when the mine-openings remain the same.

Experience has shown that with constant mine conditions the pressure produced by a fan rises as the square of the revolutions per minute, that is, if we double the speed we get four times the pressure.

It will be remembered that the mine pressure varies as the square of the velocity, so if we have four times the pressure, the velocity in the mine will increase by the $\sqrt{4}$ or 2. That is, we shall get double the air.

If we have four times the pressure and two times the air, it will take eight times the power to run the fan, provided the fan efficiency does not change; and it does not change, as we shall soon see.

FIG. 6. MULTIBLADE WHEEL

To summarize: with constant mine-openings:

1. The quantity of air in circulation varies directly with the r.p.m.
2. The static pressure varies as the square of the r.p.m.
3. The power varies as the cube of the r.p.m.

The quotient obtained by dividing the static head produced by a fan by the velocity-head at the fan-outlet bears a peculiar relation to the efficiency of the fan, and for any particular design of fan the mechanical efficiency is highest when this quotient has a certain constant value. For example, suppose we have tested a fan and found it to be most efficient when the water-gauge is 2 inches and the quantity is 30,000 cu. ft. The fan has an outlet of 10 sq. ft. Let us determine the ratio of 'static' to 'velocity'.

The velocity through the fan-outlet is $\frac{30,000}{10} = 3000$ ft. per minute.

$$\frac{(3000)^2}{(4000)^2} \times 1 = 0.56$$

This is expressed in inches of water and is the velocity-head at the fan-outlet.

$$\frac{2}{0.56} = 3.6$$

So in this particular fan, when the ratio of static to velocity is 3.6, the fan is operating at the maximum mechanical efficiency. If this fan were operated under a condition that gave a ratio of, say, 2.5, the efficiency would be lower. In all cases when the ratio was 2.5 the efficiency would have the same value.

This brings us to the useful idea that if the mine-work-

Fig. 7
Characteristic of Straight Blade Fan

Fig. 8
Characteristic of Multiblade Fan

ings are unchanged, the speed of the fan may be varied without changing the efficiency, for if we double the speed we double the quantity, and hence we double the velocity through the fan-outlet. Doubling the velocity gives four times the velocity-head. Doubling the speed gives four times the static head, hence both static head and velocity-head are multiplied by four and the same ratio remains.

Let us next study the effect of a change in the density of the air on the operation of a fan. From the formulae for centrifugal pressure and velocity-pressure we see that the static pressure produced by the fan varies directly

with the density of the air. If we double the density, we double the pressure. From our study of mine resistance we recall that the resistance to the flow of air in the mine varies directly with the density, hence the resistance doubles if the density is doubled, so the fan at constant speed will circulate the same amount of air regardless of the density of the air, provided the mine-openings are unchanged. The power to circulate the air varies directly with the pressure, hence if we double the pressure and the quantity is unchanged, twice the power is required.

The density of the air varies directly with the absolute pressure and inversely as the absolute temperature. A fan running at a given speed on a given mine will circulate the same number of cubic feet of air in the summer as in the winter. It will take less power in the summer, because the air is lighter. It will circulate the same number of cubic feet when the barometer is high as when the barometer is low. It will take less power when the barometer is low, because the air is lighter.

A fan running under exactly the same conditions of speed and mine-openings will circulate the same number of cubic feet of air at all altitudes. The higher the altitude, the less power it will take.

Our discussion so far has been confined to pressure-fans. The theory of the exhaust-fan is the same, except for the fact that the air flows into the fan at a pressure below that of the atmosphere. The pressure at the outlet of the fan is atmospheric. The average density of the air in the exhaust-fan is lower than in the pressure-fan, but there is so little difference that the fan will produce nearly the same pressure exhausting as blowing under the same conditions of mine resistance and speed.

THE EXHAUST-FAN. It will be remembered that the over-all pressure produced by the fan comes partly from centrifugal pressure and partly from the recovery of velocity-pressure. With an exhaust-fan the air usually blows out into the atmosphere at high velocity. If we put a tall, gradually expanding chimney on the outlet we can slow down the air and change a lot of this velocity-head into pressure-head, and so make this velocity contribute to the difference in pressure which the fan maintains between the inlet and outlet. A fan that is circulating a given amount of air without a chimney will, if equipped with a chimney, circulate a larger amount of air with the same power, or the same amount of air with less power.

We have discussed the sources of the pressure produced by the fan, and now let us see what makes the air flow through the fan. Suppose the outlet is closed. A particle of air caught by the fan-blade at the inlet is started whirling. The air tries to go in a straight line, but it is held to a circular course by the fan-casing. The continual forcing of the air to a circular path is what makes the pressure we call centrifugal pressure. Now if we draw some air from the fan, the air gets a chance to work out gradually along the blade until it is thrown from the tip. When the air in the blade moves outward the pressure is reduced near the inlet and the pressure existing outside of the inlet forces new air into the fan to be in turn caught by the blade.

Recent Metallurgy at Trail, British Columbia

By E. H. MASON

Many additions, improvements, and enlargements have taken place at the Consolidated Mining & Smelting Co.'s plant, at Trail, since T. A. Rickard visited the plant in 1916, and wrote an account in the "Mining and Scientific Press" of December 23 and 30, of that year, describing the operations as he then found them.

Although many smelting establishments in the United States are of larger proportions, Trail probably can boast of having the most versatile plant on the continent of North America, nor, as a matter of fact, is the equipment only of a metallurgical nature, for in its sulphuric and hydrofluosilicic acid plants Trail has branched out into the realm of what more properly should be considered as industrial chemistry. Today the Consolidated company is producing refined copper, lead, and zinc by electrolytic methods, as well as gold, silver, copper sulphate, sulphuric acid, hydrofluoric acid, and hydrofluosilicic acid.

The most extensive and by far the most interesting improvement at this plant is the development of an electrolytic zinc industry, which in a great measure has been evolved in order to treat the ore from the company's Sullivan mine, at Kimberley, in the East Kootenay district and 250 miles north-east of Trail. To attempt to give an average analysis of the Sullivan ore would be futile, for probably no two days run-of-mine would be the same; it is a heterogeneous conglomeration of compact sulphides, namely, blende, marmatite, galena, pyrrhotite, pyrite, and others, any one of which is liable to predominate, although in places comparatively clean patches of galena, blende, and pyrite are found in the mine. So closely, as a general rule, are these minerals blended, however, that under a powerful microscope a single grain that has passed a 200-mesh screen often may be seen to be composed of two, and sometimes more, minerals. The amount of gangue is negligible, rarely running up to as much as 6%. To the eye the great bulk of the Sullivan ore is an unpromising mineral that one would be prone to throw away as valueless, and even the richer samples, running between 30 and 40% in combined lead and zinc, is most unattractive stuff; and no one unfamiliar with the ore would judge that it contained anything like the amount of useful metals that the analysis reveals. Taken year in and year out, the ore probably will run between 15 and 20% of zinc and from 5 to 15% of lead, but such an enormous quantity of it has been proved that the management determined to spare neither trouble nor expense in developing a satisfactory process to treat it. S. G. Blaylock, the general manager for the company, places the probable ore-reserve safely in the millions of tons, but no definite figures can be given until further exploration has been made.

For the past ten years the company has been working

diligently to devise a process for the treatment of this ore, and, though the final process has not been selected definitively, at least two processes have been proved practicable. The process so far adopted may be divided into four distinct parts, namely, the mechanical treatment, or dressing, of the ore; the roasting of the product from the first treatment; the chemical treatment of the calcine, which, incidentally, is subjected to some mechanical treatment as well; and the precipitation of the zinc from solution.

The preliminary mechanical treatment of the ore is the only part of the process that really is still in doubt, whereas the chemical treatment, while it is likely to undergo slight changes from time to time, is quite beyond the experimental stage, for it has been proved beyond any question that, given cheap electric power, the electrolytic process for the recovery of the zinc can compete successfully with the old retort method. The company was experimenting with an electrolytic process for the recovery of zinc as far back as 1912, and it is believed that it was the first company in America to achieve success in this direction. It dropped the experimenting for a time, but took it up again before the commencement of the War, and it is not, as has often been stated, the high price of the metal during the War that made possible the evolution of the present process; as a matter of fact, the Consolidated company did not receive the high prices for zinc that were current during parts of 1916 and 1917 in the United States. The Imperial Munitions Board made a contract to take the whole of the Consolidated company's output at 15 cents per pound at a time when 27 cents per pound was being quoted for the metal in the United States.

To determine the best preliminary treatment for the ore, the company is running two experimental ore-dressing plants, the one a flotation plant, having a capacity of 400 tons per day, and the other a magnetic separation plant, with a capacity of 600 tons per day. These plants have superseded several other smaller experimental mills that were erected for the same purpose. The plants had not been tuned to capacity at the time of my visit, the greatest quantity of ore that the two of them had put through in a day being 940 tons.

The magnetic separation is based upon the removal of pyrrhotite magnetically, followed by the subsequent separation of the galena from the marmatite and blende on Wilfley tables. It has been found that the magnetic properties of the pyrrhotite in the Sullivan ore can be improved by a preliminary heat-treatment. The ore is crushed to pass a two-inch gauge, and the fine is separated from the coarse by a Mitchell electric screen; the coarse is passed through a cylindrical kiln, while the fine

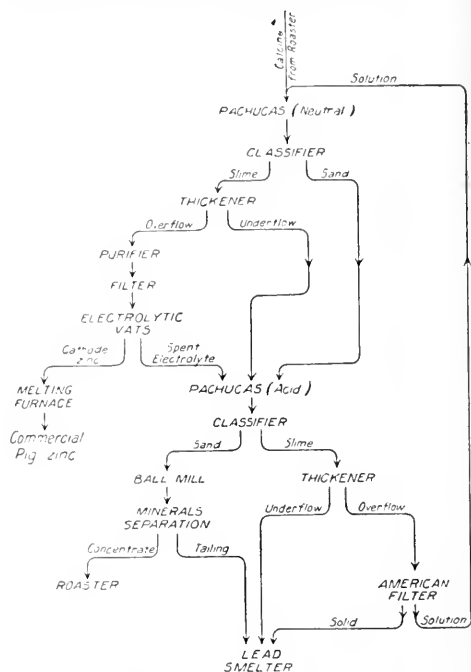

is carried by a belt-conveyor and mixed with the coarse after the latter has passed through the furnace. In this way the fine is not over-heated, as it would have been had it been passed through the furnace with the coarse. The temperature of the revolving furnace is about 1000°F. The fine and coarse are then passed through a revolving drum that is cooled by immersion of its lower part in running water. It has been found that unless the ore is thus cooled rapidly the improvement in its magnetic properties, caused by the heating, is not retained, while if, instead of being cooled in air, it is dropped directly into water the magnetic properties of the pyrrhotite are lost almost entirely. After this treatment the ore is ground in a ball-mill, and the pulp is passed over a Dings magnetic separator. This machine was designed for this particular ore, and to separate a wet pulp magnetically. Dry magnetic separation had been tried and had signally failed, but the wet method spreads the ore on a belt, enabling the magnet readily to pick up the magnetic particles, at the same time washing the non-magnetic particles out. The Dings magnetic separator consists of an endless rubber belt, similar to a vanner belt; as the pulp is conveyed along the belt it passes under a powerful electro-magnet, excited by a 15-ampere current. Between the magnet and the main belt is a narrow belt, which moves rapidly in a direction at right angles to the main belt and extends some distance on each side beyond both the belt and the magnet. The magnet attracts the magnetic particles of the pulp, attaches them to the under side of the narrow belt, which, when it gets beyond the magnetic field, drops the particles into a chute that conveys them away to be re-ground and re-passed over the machine. The pulp that passes the magnet is concentrated on Wilfley tables to separate part of the galena from the blende and marmatite; it is then thickened in Dorr thickeners, and de-watered by a five-leaf vacuum-filter. In this form it is sent to the roaster.

It must be remembered that while the plant is treating the Sullivan ore on a commercial scale, it is still in the experimental stages, and the product varies slightly from time to time with changes in the nature of the feed and with experiments that are being tried. For this reason, at the present time, the manager does not care to give out any figures as to the analysis of the product, as he considers such may be misleading. It may be said generally, however, that the concentrate is a satisfactory one, containing 25 to 30% of zinc and 12 to 15% of lead. This, it will be seen, is a great improvement on the original ore, much of which has been treated without any form of preliminary dressing other than hand-sorting for the recovery of zinc by the electrolytic method. The company is patenting the magnetic separation process.

At the other plant, the ore is crushed to pass a 20-mesh screen, concentrated on Wilfley tables, where a portion of the lead is removed, and then ground in a ball-mill to pass a 170-mesh screen. A screen-analysis of the pulp shows that 80% passes a 200-mesh screen, not more than 3% remains on a 100-mesh, and none on 45-mesh. The ground pulp goes to a modification of a Minerals Separation machine, using from 1 to 1½ pounds of mixed pine-

oil and creosote per ton of ore in a solution rendered slightly alkaline by caustic soda. At the time of my visit, the machine palpably was doing good work, for, while the original pulp was as black as coal, the concentrate that was coming away from the Minerals Separation machines was a rich reddish-brown color. The concentrate is thickened and dewatered in the same way as the concentrate from the magnetic machine.

Both methods of concentration are giving a concentrate that can be treated satisfactorily for the recovery of

FLOW-SHEET SHOWING TREATMENT OF CALCINED CONCENTRATE

both the zinc and the lead content. The magnetic separation plant does not remove the iron pyrite, and practically none of the small amount of gangue contained in the ore. On the other hand, it effectively removes all the pyrrhotite, in which form most of the iron of the ore occurs.

The products from both concentrating plants go to Wedge roasters, of which there are 13, each with a capacity of 40 tons per day. The temperature and conditions of the roast are regulated with a view to leaving about 3% of the zinc in the form of sulphate and the rest as oxide. The lead, of course, is roasted to sulphate. It has been found, as will be seen later, that if 3% of zinc is in the form of sulphate, it is not necessary to add sulphuric acid to the spent electrolyte, which is the solvent for the zinc content of the calcine; if, on the other hand, a greater amount of zinc is left in the form of sulphate, acid would have to be removed from the circuit, and, as the spent electrolyte after it has been through the pre-

THE TRAIL SMELTER; THE COLUMBIA RIVER IN THE FOREGROUND

THE ELECTROLYTIC ZINC REFINERY

precipitating-vats still contains considerable of the original zinc content, the removal of acid would cause loss and endless trouble.

The solution of the zinc is the most intricate part of the process, as upon the purity of the zinc-sulphate solution formed depends the success of the subsequent precipitation of the metal. One of the most important points is that any iron that may be dissolved in the acid pachucas (or air-jet agitators) shall be kept in the ferric state, thus ensuring its precipitation by zinc oxide in the neutral pachucas. The solution of the zinc takes place in two batteries of pachucas, each battery containing five pachucas 10 ft. in diameter and 30 ft. high. One battery is known as the 'acid' and the other as the 'neutral' pachucas. The calcine is fed into the neutral pachucas, the zinc oxide precipitating any iron, arsenic, and antimony that may be in the solution; from the pachucas the calcine and solution go to a classifier; the slime from the classifier goes to a thickener, and the overflow from the thickener is treated with atomized zinc to precipitate any cadmium and copper that may be in solution. This is filtered, the filtrate going to the reserve tank and forming the electrolyte from which the zinc is precipitated. The thickened slime together with sand from the classifier and spent electrolyte is pumped to the acid pachucas. After treatment in these until practically all the zinc has been dissolved, the calcine and solution go to a classifier, and the sand from the classifier after it has been re-ground in a ball-mill goes to an M. S. machine, which acts as a cleaner to pick up any unroasted zinc and lead sulphide, which is returned to the Wedge roasters. The lead-iron tailing from the M. S. machine is dewatered and sent to the lead smelter for recovery of lead and silver. The slime from the classifier goes to a thickener, and the overflow is pumped to the neutral pachucas. The thickened slime is dewatered and sent to the lead smelter.

The two huge electrolyzing rooms, with their 53 rows of vats, each row containing eight vats, and each vat 18 anodes and 17 cathodes, is an imposing spectacle. The anodes are of sheet-lead and the cathodes are of aluminum. Each anode and cathode has an area of 10 square feet exposed to the electrolyte; a current of 25 to 27 amperes causing the precipitation of the zinc from the solution onto the cathode. The vats are arranged in steps, each one being a few inches higher than the one immediately below it, the electrolyte being siphoned down the row from the higher to the lower vats. After it has passed through the eight vats, and has been in contact with the 136 cathodes, it is pumped to storage-tanks, ready for re-use in the dissolving-house. The passage through the eight vats removes about 60% of the zinc content. The solution, of course, is used over and over again, being brought up to the proper strength, about 55 grammes of zinc per litre, by the solution of zinc oxide from fresh calcine in the dissolving-house. From 20 to 24 lb. of zinc is deposited on each cathode every 48 hours, at the end of which time the cathodes are removed from the vats. A tap on the top of the cathode loosens the zinc deposit, and with a chisel-edged tool a workman

strips a vat of cathodes in a few minutes. The cathodes are cleaned and replaced in the vats. The zinc deposit, as a rule, is even, compact, and firm; it is conveyed to the furnace-room, melted in a small reverberatory furnace, and cast into pigs. The dross is cleaned off the surface of the zinc from time to time, and cleaned from metallic zinc in a revolving shaker. The electrolytic product is the purest form of zinc marketed.

The chemistry of the reaction is expressed by the equation

It is probable that more water is decomposed by the current than the equation demands, and that the excess hydrogen is given off at the cathode while the oxygen is given off at the anode. The oxygen decomposes the small amount of manganese salts in the solution, precipitating manganese di-oxide on the anode, and about every two months this has to be cleaned off the anodes. The manganese di-oxide is slimed and put back in the solution, with the object of oxidizing any iron in the solution to the ferric state, and thus ensuring its precipitation by the zinc oxide in the calcine. The secret of successful operation is to keep the solution pure, especially free from iron and arsenic. This is accomplished in the dissolving-house by taking care that any iron that is dissolved from the calcine in the acid pachucas is maintained in a ferric state, thus assuring its precipitation by zinc oxide in the neutral pachucas. Traces of copper and cadmium are removed by atomized zinc, the reaction being one of simple replacement.

The electrolyte is caused to maintain a continuous circuit, zinc sulphate coming from the dissolving-room, this being a neutral solution, free from impurities that affect the reaction. About 60% of the zinc content is removed by its passage through the row of vats, and the electrolyte is returned to the storage-tanks as an acid solution, ready to dissolve a fresh quantity of zinc from the calcine. The calcine contains a little lime and a small amount of magnesia, which seem to escape removal by both concentrating methods. In the leaching-room the lime and magnesia are converted into sulphate, if, indeed, the reaction already has not taken place in the roaster; whereas the sulphate of magnesia and some of the sulphate of lime go into solution. They do not interfere with the electric precipitation of the zinc, and as they become concentrated they automatically drop out of the solution. I have said that the endeavor in roasting is to get a calcine with about 3% of the zinc in the form of sulphate. A larger quantity would be more disastrous, than a smaller one, because it is simpler to add sulphuric acid to the circuit than to remove it. The electrolyte enters the zinc-precipitating vats containing about 55 grammes of zinc per litre and leaves them containing about 22 gm. per litre. This, of course, is readily brought up to strength again in the dissolving-room, but to remove some of the solution from the circuit because of an excess of acid would entail loss of zinc. It will be readily seen, too, that an excess of acid would upset the equilibrium of the circuit, preventing the precipitation of

THE ELECTROLYTIC LEAD REFINERY AT TRAIL.

THE ELECTROLYTIC COPPER REFINERY AT TRAIL.

iron, arsenic, and antimony by the zinc oxide in the calcine. A small amount of chloride is kept in the circuit to ensure the precipitation of any silver that may have been converted into sulphate in the roaster and to have gone into solution in this form.

Much of the ore being a zinc-iron mineral, some trouble was experienced in the early stages of the development of the process by the fact that a difficultly soluble zinc ferrate seems to have been formed in the roasting, but, by the proper regulation of the temperature and conditions in roasting, this difficulty seems to have been eliminated entirely.

Since the starting of the zinc plant up to the end of December last the company has produced 75,601,389 lb. of zinc, 30,743,461 lb. of which was produced during the 15 months ended December 31, 1919. The period of 15 months, instead of 12 months, is given here and elsewhere in this article because last year the company changed the date of the termination of its fiscal year from September 30 to December 31.

No great changes have taken place in the electrolytic lead-refinery since Mr. Rickard's visit. The metallurgical practice has been improved in many small details, and better work has been done than at any period during the past ten years. A uniformly high-grade product has been produced at a cost well below that which could be obtained by the Parkes process, working on the same tonnage. During the 15 months ended December 31, 1919, 41,711,147 lb. of lead was produced, bringing the total production since 1894 up to 538,882,617 pounds.

The copper refinery was dismantled at the time of my visit. Just at the present time, ore is not being shipped from the Consolidated company's Rossland mines, and concentrate from the Canada Copper Corporation's plant, at Allenby, which the Consolidated company has arranged to treat, is not expected to be coming in before August. The present, therefore, was an opportune time for enlarging the refinery plant, and the work of construction is well in hand. The old refinery had a capacity of 20 tons of refined copper per day; this is being increased to 50 tons per day. A copper-rod rolling-mill of like capacity is being added to the plant. The old anode-casting furnace has been torn down, and a new one of increased capacity is being erected. A satisfactory process has been demonstrated for the treatment of the lower-grade gold-copper ores of the company's Rossland mines, and, as a result, many years have been added to their life. A flotation mill of 200 tons daily capacity was run for several months on these ores, and proved beyond all doubt that they can be concentrated at a reasonable cost and with good recovery. Plans are well under way, and the ground has been broken at Trail for a concentration plant with a daily capacity of 1500 tons to treat these ores. For the 15 months ended December 31 the company produced 6,933,962 lb. of copper, bringing the total produced since 1894 up to 89,964,275 pounds.

The gold and silver refinery has been reconstructed and brought up to date. The refining of copper by the electrolytic method differs from that of lead in that, as the copper dissolves, the gold and silver, together with

the impurities in the metal, become detached from the anode and fall to the bottom of the vat. In the electrolytic refining of lead, on the other hand, most of the precious metals and the impurities adhere to the anode in a spongy form; consequently all the vats in the copper refinery are provided with traps in the bottom, through which the sludge is removed to receptacles below the vats. In the lead refinery only the end vat of each row has such a trap, the sludge being shoveled down the row into the last vat. The sludge passes through this trap onto a filter, where it is washed, and as much water as possible removed by a vacuum below the filter-bed. The sludge passes to a series of dryers that are arranged under the flue and are heated by the waste heat from the refinery furnace. When dry, the sludge is melted in a small reverberatory furnace and cast into bars. These bars, of course, contain all the gold and silver, together with a considerable amount of lead and copper, as well as impurities that were contained in the original anodes, the principal of which is antimony. The bar metal is melted and scorified in the same furnace until practically only gold and silver remain. The bullion is cast into bars. The slag is melted, made more liquid, and cleaned in the same furnace until it is free from shots of metal, and in this state it is either re-treated for precious metals or sold for its precious metal and antimony content.

The bars of bullion are parted by the sulphuric acid method in cast-iron kettles, 60° B. acid, which is made at the works, being used. When the silver is completely dissolved, the gold is removed, washed, dried, and melted in a crucible in an ordinary gasoline melting-furnace. The silver sulphate is diluted, and the silver is precipitated as cement silver by pig-copper. The cement silver is washed, dried, melted in a small oil-heated furnace, and cast into bars. The copper, which goes into solution as sulphate, replacing the silver, is concentrated in vats, and the copper sulphate is crystallized on strips of lead. During the 15 months ended December 31, 1919, the Consolidated company produced 59,605 oz. of gold and 1,782,025 oz. of silver, bringing the total since 1894 up to 1,891,443 oz. of gold and 30,496,067 oz. of silver.

In closing this article I desire to express my sincere thanks to the staff of the company for their courtesy in giving me access to the plant and in helping me in every possible way.

For some time past no copper, nickel, silver, or gold has been coined in Germany; iron and aluminum are used instead. During January 1920 the following subsidiary coins were minted and circulated: 3,340,870 marks worth of 50-pfennig aluminum pieces; 1,010,856 marks worth of 5-pfennig iron pieces. The total circulation of iron 5-pfennig pieces now amounts to 44,642,595 marks; circulation of iron 10-pfennig pieces, to 22,050,904 marks; of zinc 10-pfennig pieces, to 44,244,104 marks; and of 50-pfennig aluminum pieces, to 8,597,904 marks.

THE Anaconda Copper company is testing a moveable drill-bit intended for use on a shaft of steel of cheaper grade. If found practicable the plan should save money.

A Volumetric Method for Determination of Tungsten

By GEORGE M. ENOS

*Those familiar with the usual gravimetric methods for the determination of tungsten, realize not only that there is much room for improvement in these methods, but that an accurate volumetric method would effect a great saving in time. Even a skilled analyst cannot complete an analysis by some gravimetric methods in less than ten or fifteen hours. It was with the idea of finding a shorter and at the same time accurate method that this research was conducted. Previous attempts to secure a suitable volumetric method have not been satisfactory and none is accepted as standard so far as I am able to ascertain.

When tungstic oxide, WO_3 , is reduced by heating to dull redness in a current of hydrogen, WO_2 is formed, which can be still further reduced to metallic tungsten, if the temperature is raised. WO_2 is a brown powder, and when formed in this manner is not stable in the presence of oxygen and must be cooled in a current of hydrogen. Tungsten may ordinarily be detected in minerals by boiling the finely powdered material with concentrated hydrochloric acid until insoluble yellow tungstic acid is formed. Zinc or tin is then added and if tungsten is present in appreciable amounts, a blue color appears in the solution or the yellow residue turns blue, due to reduction by the nascent hydrogen. This is the usual qualitative test. Reduction may be hastened by heating; if zinc be the metal used, the reduction may be continued until the brown WO_2 is formed. The blue color is believed to be due to the oxide W_2O_3 ; or more probably to a mixture of WO_2 and WO_3 . The brown color of the solution is due to the presence of WO_3 in suspension, it will settle out if exposed to the air. It is probable that some of the WO_3 is re-oxidized by air to WO_3 which is appreciably soluble in concentrated mineral acids, particularly hydrochloric.

Experiments tried showed that zinc is probably the only common metal capable of reducing the WO_3 entirely to WO_2 . Aluminum, tin, and stannous chloride in acid-solutions were tried, but the reduction gave solutions that showed only the blue color, even after long continued boiling. Titrations tried on the blue solution produced by reduction with aluminum in acid-solution, gave no agreeing results, indicating that a compound of definite composition was not present in the blue solution. The outline of the proposed volumetric method consists in acidifying a solution of an alkaline tungstate with sulphuric acid and the reduction of the tungsten from the hexa-valent to the tetra-valent state in acid-solution by means of a Jones reductor, and finally oxidizing the tungsten to the hexa-valent condition with a standard solution of potassium permanganate. This method has proved successful when certain precautions, which have

been carefully worked out, are observed. The accompanying cut of the Jones reductor shows the action of the solution, with the stages of reduction at different points indicated by the color changes. There is no reasonable doubt as to the completeness of the reduction.

OUTLINE OF THE PROCEDURE. The tungsten is obtained in solution as an alkaline tungstate by any of the standard fusion methods. The removal of interfering elements may be accomplished by various methods. It may be pointed out here that in the procedure given below, that iron, calcium, magnesium, and manganese will be removed by the filtration, and any copper or tin will be precipitated on the zinc in the reductor.

The following method is satisfactory in most cases:

Fuse 2.5 gm. of the finely powdered sample with 3 to 5 gm. of $NaKCO_3$ and 0.5 gm. of KNO_3 for not less than one-half hour, in either a platinum or a porcelain crucible. Dissolve the fused mass in hot water. Filter.

With some ores it may be advisable to make use of an alternative method of getting the material into solution. Where a large weight of sample is taken it is advisable to dilute the alkaline solution and take aliquot parts to be acidified and titrated.

THE REDUCTOR

Make the filtrate distinctly acid with H_2SO_4 and add 5 to 10 cc. in excess. The solution at this point should not exceed 100 cc. for best results. Heat to 80° to $90^\circ C.$, and pass through the Jones reductor at a moderate rate. The reductor should be washed with dilute H_2SO_4 and the washings discarded before the solution is passed through it. The solution above the zinc should show a deep blue color, and, when emerging from the zinc-column, a deep brown color. Wash with 50 to 150 cc. of dilute H_2SO_4 , being sure that all the brown precipitate of WO_2 is washed from the reductor. Finish washing with distilled water. Run the wash-solutions into the same flask as the main solution. Titrate at once with one-tenth normal $KMnO_4$. The percentage of WO_3 can then be calculated from the following equation:

$$\frac{\text{cc. K Mn O}_4}{\text{wt. of sample}} \times \frac{232}{2} \times N \times 100 = \% WO_3$$

To standardize, pure WO_3 was prepared by dissolving Merck's C.P. WO_3 in NH_4OH , precipitating with HNO_3 ,

*Abstract from the 'Pahasapa Quarterly'.

drying, and then heating to about 500 C. This material was kept in an air-tight bottle. The standardization of the procedure was then worked out on the oxide prepared in this way. The results are given in the following table.

Sample	W, by volumetric method %	W, by calculation %
Pure WO ₃	80.02	79.3
Pure WO ₃	77.8	79.3
Pure WO ₃	79.6	79.3
Pure WO ₃	79.5	79.3

Several other determinations were carried out on different types of tungsten ore and the results are compared with the gravimetric results obtained by Ledoux's ammonia method in the following table:

	WO ₃ , by volumetric method %	WO ₃ , by gravimetric method %
Scheelite (1)	59.51	59.60
Scheelite (2)	79.9	76.67
Tungsten sand	2.8	2.8
Wolframite (1)	62.6	62.5
Wolframite (2)	20.41	20.50
Wolframite (3)	45.8	45.95

NOTES ON THE PROCEDURE. Running dilute acid through the reductor first, produces an atmosphere of hydrogen, thus preventing oxidation of the tungsten in solution in the filter-flask by the oxygen of the air. The flask should not be disconnected from the reductor until everything is in readiness to titrate.

The solution passing through the reductor must contain enough acid to liberate hydrogen freely. No harm results if the solution shows a slight turbidity.

The temperature of the solution should be about 80° C.

The reductor must be washed clear of WO₃ with dilute H₂SO₄. The best results are obtained when a 2 or 3-normal solution of H₂SO₄ is used.

The volume for titration should not exceed 300 cc, and should not be cooler than 40° to 50° C.

The end-point in titrating is reached when the first permanent pink tinge appears. It is necessary to run a blank to determine the true end-point, since it requires an appreciable amount of permanganate to produce a pink tinge in 200 to 300 cc. of water acidulated with H₂SO₄.

The entire run on an ordinary ore does not take longer than three hours.

This method does not need platinum dishes, as no difficulty is encountered by fusing in porcelain, and no long evaporations are necessary.

The tungsten solution may be run into an excess of ferrie sulphate where an equivalent amount of ferrous sulphate is formed which may then be titrated with KMnO₄.

It is also practical to run WO₃ into a measured quantity of KMnO₄, the KMnO₄ being in excess. Titrate the excess permanganate with standard ferrous sulphate.

OWING to the scarcity of radium—which is now priced at \$77,864 per gramme—and the failure to discover new sources of supply, it is feared the shortage will become

exceedingly acute. In the meantime, the Radium Institute in Great Britain is reported to be preparing radium for use in medical research by a strange method. A weak solution is made which gives off radium emanations; these, which are only detected by delicate instruments, are bottled into tiny glass phials and corked, and the phials are sent to medical men. It is stated that the efficacy of such bottled emanations lasts one week.

Smelting of Cyanide Precipitate

A feature of the refining at the Golden Horseshoe Estates mill in Australia is the use of gas-carbon in a Faber du Faur furnace. Gas-carbon is a by-product from gasworks and is practically pure carbon. It has great advantages as a fuel when compared with the best English coke, as it saves a considerable amount of labor, makes a large reduction in the fuel consumed, gives a higher temperature, and does not form any clinker in the furnace or on the fire-bars. When lighting the furnaces an abundance of wood must be used, and the gas-carbon fed in gradually until it is fully charged. It is necessary to light the furnaces about four hours before they are required. No addition of fuel is required to complete the smelt, and when the charge has been poured the fire-bars are withdrawn and the remaining gas-carbon is quenched with water, after which it can be used again. The consumption of fuel amounts to 1½ lb. of gas-carbon to 1 lb. of precipitate.

The precipitate contains:

	%		%
Insoluble	2.45	Lead oxide	9.05
Gold	21.06	Zinc oxide	21.65
Silver	19.98	Calcium oxide	6.80
Iron oxide	3.45	Magnesium oxide	0.61
Aluminum oxide	1.37	Sulphuric anhydride	6.64
Copper oxide	3.49		

To 100 parts of precipitate is added 30 parts of borax-glass, 8 parts of quartz sand, and 7 parts of manganese di-oxide. This is thoroughly mixed on a concrete floor, but not sieved, as is sometimes practised, and is charged into the crucible by means of a specially designed chute. A No. 9 plain salamander erneible is used. It usually requires 2½ hours to complete each fusion, which, together with fluxes, weighs about 300 lb. Before pouring, the contents of the crucible are thoroughly stirred, the slag is collected in a slag-pot similar in design to those used in smelting works. The gold is poured into conical molds, any adhering matte is scraped off, weighed, and the bullion is re-melted in a No. 30 salamander erneible. When the bullion is molten, nitre is added and stirred thoroughly; the slag is thickened by the addition of mabor and skimmed off. These skimmings are subsequently treated by amalgamation. The bullion is cast into ingot molds which have previously been heated and coated with lamp-black by turning them upside down over some burning oily waste. The slag is removed from the bars while they are red hot, and they are further cleansed by plunging into a pickle bath, and then washed with fresh water. Finally they are scrubbed with carbonate of soda, washed, dried, and weighed. The fineness of the resulting bullion is gold 533.1, silver 435.6, and base 31.3.

The Fahrenwald Flotation Machine

By FRANCIS A. THOMSON

Flotation machines are numerous. One criticism that may be leveled at nearly all of them, whether of the agitation or pneumatic type, is their high consumption of power. In the agitation type of machine this results from the fact that the entire pulp is kept in an unneces-

	Kw-hr. per ton of ore treated
Pneumatic machine	2 to 4
Janner	4 to 8
M. S.	4 to 6

As showing the relative consumption for various op-

DETAILS OF LABORATORY MACHINE

sarily exaggerated state of violent commotion in order to effect aeration and circulation, together with sufficient mixing to ensure complete distribution of flotation reagents and general homogeneity of the cell contents.

In the pneumatic machine, consumption of power is due mainly to the inherent inefficiency of air-compression itself. The following figures are deduced from current practice:

erations in a mill the following figures have been calculated from published descriptions of the Anaconda plant:

Operation	Kw-hr. per ton of ore
Crushing and grinding	8.8
Gravity concentration	0.9
Flotation concentration	4.8
Conveying, elevating, dewatering, etc.	3.8

The contrast between the power used for flotation and for gravity concentration is startling. Other comparisons of this kind would be interesting.

The consumption of power in the agitation type of machine can be reduced only by decreasing the amount of pulp under agitation at a given period. This is done in certain machines, such as the Ziegeler and Bunker Hill, in which only a portion of the pulp undergoes agitation at any one time.

A second consideration in the operation of flotation

parent than real and I am inclined to think that the Fahrenwald machine will in practice show several advantages not possessed by either of the other machines mentioned.

Fig. 1, 2, and 3 show the essential features of the machine. It consists of a stationary hollow tube *A*, to the lower end of which the upper and lower housings *B* and *C*, enclosing the impeller *D*, are suitably secured. The impeller is simply a revolving disc with vanes above and below; these vanes are set 90° apart and tangent to a

FIG. 4. FOUR-CELL MACHINE OF COMMERCIAL SIZE

machines is that the spitzkasten or frothing-chamber shall be as quiet and undisturbed as is consistent with proper aeration, circulation, and mixing.

These desiderata are in large measure fulfilled in a machine that has been developed in our* laboratory by A. W. Fahrenwald, a member of our faculty. The laboratory machine has attracted a good deal of attention and several experienced operators after seeing it in operation have arranged to have it duplicated for their personal use in testing.

From the accompanying drawings it might seem that the machine bears a close resemblance to the Ruth and Groch type. This resemblance is, however, more ap-

parent than real and I am inclined to think that the Fahrenwald machine will in practice show several advantages not possessed by either of the other machines mentioned. Fig. 1, 2, and 3 show the essential features of the machine. It consists of a stationary hollow tube *A*, to the lower end of which the upper and lower housings *B* and *C*, enclosing the impeller *D*, are suitably secured. The impeller is simply a revolving disc with vanes above and below; these vanes are set 90° apart and tangent to a circle one-third the diameter of the entire disc. There is a suitable hub on the upper side of the impeller by means of which it is secured to the solid impeller-shaft *E*, the other end of the shaft projects from the upper end of the pipe, and power is thus applied to it. This solid impeller-shaft revolves inside the hollow tube and is carried in suitable ball-bearings *R* secured within this tube. There is a T-connection just above the frothing-level through which air, oil, gas, or other substances may be admitted. Admission of air or other gas through this opening is under complete control of the operator through manipulation of valve *H*. Additional openings for any purpose may easily be provided. The lower housing *C* carries the suction-pipe *J*.

The operation of the machine is evident. Power is ap-

*The writer of the article is Dean of the School of Mines, at Moscow, Idaho.

plied to the impeller, and, as soon as the valve *H* is opened, air is drawn in on the upper side through the hollow tube and around the shaft, at the same time pulp is drawn up through the suction-pipe *J* and both air and pulp are delivered simultaneously at the periphery of the impeller. Circulation, aeration, and mixing are thus effected with a minimum expenditure of energy. The upper side of the impeller runs in air practically free from friction, the lower side of the impeller is in contact with but a small fraction of the pulp and there is none of the wild vortical, swirling, and eddying action characteristic of the usual paddle-agitator machines. Without the vortex in the paddle-agitator there could be no aeration, in the machine here described there is no occasion for a vortex and none is formed.

Efficient aeration with finely disseminated air-bubbles is the result of the action of the impeller. Air is sucked in by the action of the upper side of the impeller and as it leaves the housing it is drawn into the sheet of pulp which is continuously being discharged from the lower side of the impeller, thus affording maximum entrainment with minimum disturbance.

Fig. 4 shows the general construction of the machine as sold. A four-cell machine is shown, any number of these may be built in series to handle any particular given ore. Each cell is a unit and its operation may be cut out without greatly affecting the working of the machine. The aerating and circulating unit described above is so attached that in case of trouble it can be readily removed and replaced by a new one. The amount of aeration can be controlled in the various cells, which is of great importance in differential flotation.

The laboratory machine is designed to treat a 1000-gm. charge in a pulp-dilution of 4 of water to 1 of solid by weight. This is a convenient weight upon which to base calculations. Power is applied to the impeller with air-valve closed, and water is added to the machine until it reaches a level half an inch above the impeller. This forms a closed circuit of the pulp through the impeller from lower tube *J* and back to the main body of the pulp. The ore is now added to the machine, which brings the level up a little. With the pulp level $\frac{3}{4}$ to 1 inch above the impeller the maximum mixing effect is obtained. When the pulp has been thoroughly mixed with the reagents to be used, water is added to bring the dilution up to 4:1. This brings the pulp level up to within three inches of the overflow-lips.

The air-valve *H* is then manipulated to give the proper aeration, which can be adjusted to a nicety and a froth of practically any depth can be had. By regulating the valve, the froth can be made to overflow into the pan at any desired rate. This duplicates the automatic froth-overflow feature of the pneumatic type of machine. The froth can also be held below the discharge-lip and skimmed off as in other testing machines if for any reason this procedure is preferable.

If the ore is ground in a ball-mill, the reagents can be ground in or mixed with it and pre-agitation in the testing machine is unnecessary.

The Coke Industry During 1919

The outstanding features of the coke industry in 1919 were the great slump in demand that followed the Armistice and a remarkable increase in the proportion of by-product coke as compared with beehive coke. According to preliminary estimates made by F. G. Tryon, of the U. S. Geological Survey, the total production of coke in 1919, including beehive and by-product but excluding gas-house coke, was 41,821,000 net tons, a decrease, when compared with the production in 1918, of 11,657,000 tons, or 21%. The decrease was confined almost entirely to beehive coke, the production of which fell off 36%. The output of by-product coke decreased only 3%. The output of by-product coke consequently exceeded that of beehive coke for the first time. In 1918 about 46% of the total coke made in the United States was produced in by-product ovens and 54% in beehive ovens. In 1919 the proportion was reversed, 56% coming from by-product and only 44% from beehive ovens. The year 1919 thus marked a turning point in the history of coke manufacture in the United States. These figures are preliminary only and will be revised when the annual statistical canvass is completed.

The iron-furnaces are the great customers of the coke industry. In 1918 they consumed 45,704,000 net tons of coke, or 81% of the total output of beehive and by-product coke, combined. In 1919 the production of pig-iron fell off 22% and the demand for coke declined in proportion. The reaction was especially felt by the producers of beehive coke. With the growth in the output of by-product coke the beehive-coke industry is likely to become more and more an auxiliary source of fuel, carrying the peak load in times of extreme activity and being correspondingly restricted in times of depression. The post-war slump in the demand for beehive coke began to be seriously felt about March 15, and reached its lowest point in May. Thereafter production slowly recovered, only to be further interrupted by the steel workers' strike and the coal strike. As a result the production of beehive coke fell off 36% in 1919. All districts shared in the decrease. The total output in 1919 is estimated at 19,650,000 net tons. The total output of coke made in by-product ovens in 1919 was 25,171,000 net tons, a decrease, as compared with 1918, of 827,000 tons, or 3%. The increase was general and affected all States except New Jersey, Ohio, and Pennsylvania. The effect upon production of the decline in demand for by-product coke was largely counteracted by the completion of new plants. The rate of production was higher during January, February, and March than during the remainder of the year. During the last quarter the output suffered, as did that of beehive coke also, from the combined effects of the steel strike, which restricted demand, and of the coal strike, which curtailed the supply of coal.

During 1919 there were completed and put in blast 1228 new by-product ovens, of which 718 were at new plants and 510 were extensions at existing plants. One new State, Rhode Island, entered the ranks of by-product

coke producers in January, when the Providence Gas Co.'s plant was completed. During the year 128 ovens were either abandoned or were so re-built as to be classed as new ovens. On January 1, 1920, there were in course of construction 853 ovens, which were scheduled to come into operation by July 1, 1920. The maximum capacity of the by-product plants has been estimated at 27,000,000 net tons of coke at the beginning of 1918, 33,700,000 tons at the beginning of 1919, and 39,500,000 tons at the beginning of 1920. These annual capacities are estimated on a basis of 100% operation. In actual practice, however, an average operation above 90% cannot be assumed for the country as a whole, and the safer figure of 85% would appear better justified by experience. Under an operation of 85% the present capacity of the country would be about 33,600,000 tons. Completion of the plants now under construction may raise the capacity to approximately 43,300,000 tons, or 36,800,000 tons under an operation of 85%. Estimated according to the quantity of by-product coke produced in 1919—25,171,000 tons—the quantities of by-products recovered during the year amounted to 668,200,000 lb. of ammonium sulphate or equivalent, 251,000,000 gal. of tar, 84,800,000 gal. of crude light oil, and 367,700,000 cu. ft. of gas.

Production of Manganese

A preliminary statement of the production of manganese in the United States in 1919 and of the general present conditions of the industry has just been compiled under the direction of H. A. C. Jenison, of the U. S. Geological Survey. The general decline in the domestic production of high-grade manganese ore, which began early in 1919, continued throughout the year. During the last quarter the shipments of high-grade ore containing 35% or more of manganese amounted to only 4069 long tons. Most of this ore was shipped from Montana. During the same period the shipments of manganiferous ore containing 10 to 35% of manganese amounted to 120,243 tons. Of this quantity about 96,221 tons came from Minnesota, 18,240 tons from Nevada, 3965 tons from Michigan, and 1000 tons from Virginia. The shipments of ore containing 5 to 10% of manganese amounted to 24,921 tons, of which 24,597 tons came from Minnesota. The decline in imports that was noted during the summer of 1919 continued through the last quarter of that year, and the first two months of 1920 is marked by a further decline. The same conditions as prevailed in 1919 have persisted to the present time, and to them have been added low rates of exchange and domestic and foreign labor troubles. These conditions and the unfortunate state of European industry in general have seriously affected the foreign market for American steel and steel products.

In spite of the decline in the domestic production and in the imports of manganese the production of steel during the last few months has been made possible through the utilization of the stocks that accumulated during the period of large production. These stocks were sufficient

to meet the requirements of the steel industry for several months without further imports or domestic production. The reduction of the stocks has been accompanied by an increase in the price of nearly all grades of manganese ore and alloys, but, contrary to what might be expected, this increase in price has only slightly affected the domestic production, and imports have declined still further. According to the United States Shipping Board, there has been no shortage of ships nor is there any likelihood that there will be, and the freight-rates on imported manganese ore have decreased rather than increased. According to the best information available there has been no shortage of labor in the manganese-producing countries and, except in Russia, no apparent reason for the decrease in the export of ores to the United States. Since the 'nationalization' of the manganese deposits in regions dominated by Soviet Russia ore can be produced only by or under the direction of the 'Government', and none has been produced. Under normal circumstances the condition in Russia should have stimulated exports to the United States from Brazil, India, Mexico, Cuba, and Central America. With decreasing freight-rates, sufficient ships, and favorable internal conditions in manganese-producing countries, the reason for the decrease in imports can only be inferred. The practical discontinuance of imports and the almost negligible domestic production has enabled the holders of stocks to dispose of them at increasingly favorable prices. Large importation of foreign ore and alloys will no doubt be resumed when the stocks held in this country are sufficiently reduced. With any large increase in domestic production there would be probably a contemporaneous increase in imports which would bring the domestic ore into unfavorable competition with foreign ore. The continued critical condition of industry throughout the world introduces another factor which should be carefully considered. The market and the industrial conditions are sufficiently uncertain to make the resumption of domestic production a matter to be considered with great caution.

THREE tin mines in Bolivia have recently been acquired by American interests. The properties are known as Caracoles, Huanchaea de Inquisivi, and Paenai, and are situated in the Department of La Paz, at a distance of about 65 miles from the Eucalyptus station of the Bolivia railway between Oruro and La Paz. The total area of these properties, which lie at an altitude of about 17,000 ft. above sea-level, is about 4000 hectares, and deposits are known to average from 10 to 15% tin. Already a centre of operations has been established at Eucalyptus, where 26 American engineers are engaged in the preliminary construction work both at the mines and on the road between the railroad and the properties. It is said that a road suitable for auto-trucks is to be built by the company and a hydro-electric plant for supplying the mines with power is to be one of the first projects to be carried out. Heavy machinery for this part of the development has already been purchased.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

RECEIVER ASKED FOR MILE WIDE COPPER CO.

JOHNSON.—The Keystone Copper Co. recently purchased 200,000 ft. of lumber for the construction of the new mill, and \$50,000 worth of machinery for the mine and mill has been ordered. The shaft has now reached a depth of 635 ft. and on the 125-ft. level a large body of 2 to 10% copper ore carrying gold and silver has been opened. It is expected that the mill will be in operation by the end of the year.

KINGMAN.—J. G. Keseler and associates netted \$229 from a shipment of 1600 lb. of ore obtained from location-work on a rich silver-lead deposit north of the Catherine mine on the Colorado river. The Hackberry Consolidated Mining Co. has purchased all of the equipment on the Senate Silver mines and it will be moved to the Combination property, which is situated to the north on the same vein as the Hackberry Consolidated Silver Mines Co. Sam Martin is superintendent of the Com-

binations. The shaft is north of the old orebody. Some copper ore has been found in the shaft. This property was the old McCracken mine.

A consolidation of the Arizona Rex and the Arizona Midway Mining Co. is being planned. These properties adjoin and are in the Silver Creek district, four miles north of Oatman.

TUCSON.—A receiver has been asked for the Mile Wide Copper Co. by the stockholders, who allege in their complaint that Charles P. Reiniger, president of the Mile

MILL OF THE PHELPS DODGE CORPORATION, AT MORENCI

bination mine. It is reported that a streak of ore assaying \$1100 over a width of eight inches has been cut in the new shaft of the Gold Button mine at a depth of 40 ft. This mine is in the Aubrey district in the Wallapai mountains. What is said to be one of the richest discoveries reported from the Wallapai mountains has been made on the Diamond Joe mine at a depth of 300 ft. Former operators of the property lost the ore on the level above through faulting. Sinking to the 300-ft. level, a small seam was picked up, and drifting on this has opened ore having a width of 18 in. The ore carries some copper and lead.

Sinking is now being continued in the 400-ft. shaft of the Campbell Consolidated mine in the McCracken moun-

SHATTUCK-ARIZONA MINE AT BISBEE

Wide Copper Co., capitalized at 1,000,000 shares at \$5 each, had used the company as a trustee to collect on the sale of the stock of the company, whose total capital stock had been transferred to him and others. The court is asked to decree that Reiniger stands in fiduciary relation to, and to be trustee for, the Mile Wide Copper Co.; that the issuance of the capital stock to Reiniger be declared null and void; that plaintiffs be decreed subscribers to the capital stock of the defendant company and entitled to stock there; and that a receiver for the protection of the rights of the parties therein pending be appointed. It asks further that Reiniger be compelled to account to the receiver for the bona fide stock and all real and personal property in his hands belonging to the company and purchased with money derived from the sale of its stock, and to turn over to the receiver all moneys received by him arising from the sale of stock; and that all shares of stock held by Reiniger be delivered to the company and cancelled.

The Gray Metals Co. has been formed to take over

seven claims in the Huachuca mountains owned by Douglas Gray, of Tombstone. This silver-lead-zinc property has been under development for the past seven years and there is considerable equipment on the property. Prominent business men are behind the new undertaking.

COLORADO

NEW EXPLORATION PLANNED FOR CRIPPLE CREEK.

CRIPPLE CREEK.—Exploration by diamond-drill of the area north-east of the present producing section, by a syndicate of prominent operators, has been arranged and will commence as soon as the contractors have their equipment on the ground. The theory advanced by W. H. Trask of Denver, owner of the Pride of Cripple Creek mine on Ironclad hill, is that approximately 5000 acres in the Gillet section, has a granite capping overlying the eruptive, resulting from a series of flows or slides from the vicinity of Pikes Peak, while the crater was still open and contained molten material. This theory was presented to George Stahl, general manager for the Vindicator company, and to A. E. Carlton, with the result of the organization of a syndicate backed by the Cresson and Vindicator companies, Bulkeley Wells, manager of the Smuggler Union at Telluride, Harry W. Robinson, well known mining attorney of Denver, and others. Acreage has been acquired and contract for drilling let. If the eruptive is entered at reasonable depth below the granite, a working shaft will be sunk and extensive horizontal holes drilled from the bottom of the shaft to find possible ore. Development work and operation will be under the direction of W. R. Ryan, general superintendent for the Vindicator company. Egildson Brothers, diamond-drill contractors of Wyoming, have been awarded the contract and their outfit is now on the way to the district.

Ore sampling 8 oz. gold per ton has been opened up south of the Jerry Johnson shaft at the 6th level, 750 ft. from the surface by F. G. Horn, lessee. This ore is the farthest south yet discovered in the mine. The War Eagle Consolidated Mines Co. has erected an ore-house near the shaft of the Blue Flag company on Raven hill and is hoisting ore from the shoot on War Eagle territory opened up at the Moffat tunnel level, through the Blue Flag shaft. On the South Burns claim of the Acaia company, Bull Hill, the company has opened up a strong vein of milling ore at the 1400-ft. level. Development is in progress by H. L. Le Brun, lessee, at the 1500-ft. level. Milling ore has been opened up in the New York tunnel on the western slope of Bull hill. The property is operated under lease by Colorado Springs capitalists. Stewart Cox and associates have opened up shipping ore on the Pinto mine of the Free Coinage company, on what is believed the extension of the Maloney vein found on the Empire ground, Isabella Mines company, adjoining.

SILVERTON.—A large tonnage of silver-lead ore will be shipped from the Mountain Queen in California gulch, from the orebody opened last fall. The shaft was re timbered before the winter shut-down, in readiness for

heavy production this year. A Cleveland, Ohio, syndicate operating the Fraction is breaking ore and will start shipping as soon as the new hoisting plant is completed. The Seaton Mountain Mining & Leasing Co. is mining ore with high silver-lead content and shipping to the smelter. Both the Cleveland and Seaton managements are paying a bonus to every man working 30 days.

BRECKENRIDGE.—Gold ore has been shipped from the Dunkin by lessees, and the Nels Olstrum lease on the Iron Mask is shipping lead carbonates. The Breckenridge Mining & Cyanide Co. shipped a consignment of rich ore from the Fox Lake and Ira Roberts properties in Yuba Dam flats to the A. & V. smelter at Leadville. Prospectors are getting out in the hills as the snow melts and are preparing to work on mines that produced silver ore when last operated.

MICHIGAN

SENECA CONTINUES SINKING.

Houghton.—Seneca's shaft continues to go down toward the 5th level. The output is averaging better than 350 tons per day now. Of this, 250 tons is coming from the openings on the 3rd and 4th levels. All four of these openings are in 120 ft. from the shaft and the quality of the ore persists. It is fair to say that the general run of material mined during the past ten days will show 25 lb. per ton. When the 4th level laterals are run, further stoping will commence and within 30 days the Seneca tonnage will be derived from the underground openings, provided they maintain the same grade, as seems altogether likely.

At the Gratiot the drift on the 15th level to the south has attained 190 ft. from the shaft. It continues in material which is to be tested at the stamp-mill in separate tests. This lode appears to have the characteristics of the Kearsarge, including much copper. Just what it will average is a matter of much interest and some speculation.

Quincy is building a crushing-plant at the smelter. This will be utilized for the purpose of grinding the brick that is taken from the inside of the furnaces. This brick becomes impregnated with copper, following long continued usage. The experiments have shown that this ground-up brick not only produces considerable copper, but the product makes an entirely satisfactory sand to use in new charges in the furnaces.

Calumet & Hecla is extending its electric-power lines for the purpose of carrying high-power voltage to the associated mines at the north end of the county. These lines now are being run from Laurium toward No. 4 Kearsarge and later on will go to the Ahmeek and the Allouez mines. The more general use of electric trams underground requires additional power underground. The Ahmeek has added to its use of electric trams; so has the Allouez, and at the old Osceola the long hauls running over into the La Salle territory, which continues to maintain a good tonnage of the best grade of Osceola lode 'rock' that is taken out anywhere in the district, require electric power. The only construction

work that Calumet & Hecla is doing at present is underground haulage on the conglomerate at the 3rd level. The flotation-mill improvement and the proposed remodeling of the smelter have been held in abeyance owing to the difficulty in securing labor and the high cost of material entering into the construction account.

At the new Baltic shaft of the Arcadian Consolidated property the cross-cut on the 500-ft. level back to the vein is well under way, following the unwatering of the shaft. There is reason to believe that the vein will be tapped within a week, if the present rate of progress is maintained. On the 400-ft. level work will be resumed at once. This is the level where the showing of copper

company. Work on the 300, 400, 500, and 625-ft. levels, where large tonnages of ore have recently been opened, will be the first step in this program. According to expectations the capacity of the mine will be doubled. This will give employment to 250 men instead of 150 employed at present.

NEVADA

DEEP SINKING PLANNED FOR ARROWHEAD DISTRICT.

ARROWHEAD.—The Arrowhead shaft has been sunk 45 ft. from the 175-ft. level and it is to be continued to 300 ft., with a level at 250, according to present plans. The ore-shoot is 5 ft. wide and assays 45 oz. silver and \$4

THE SAN JUAN MOUNTAINS, COLORADO

was so spectacular. Arcadian had a little trouble getting coal, but this problem has been solved, temporarily at least.

MONTANA

WORK SUSPENDED AT NEIHART.

NEIHART.—The mines in this district are idle following a demand for a wage-increase of 50c. per day. The men walked out without giving the mine-owners any notice of the strike action. The mines affected are the Cascade Mines & Mills Co., Neihart Consolidated, Neihart Silver Mining Co., and the Florence and Gault properties. The mine-owners followed the action taken by the Butte mines by immediately announcing that no more I. W. W. members will be employed in the district. All future applicants will be thoroughly investigated along these lines. It is claimed that the leaders of the local strike were also active in the recent strike of miners in Butte.

H. G. Palsgrove, of Denver, has been appointed manager of the Cascade Silver Mines & Mills Co. to carry out the development program which has been outlined by this

gold at the bottom of the shaft. Shipments that have an average value of \$75 per ton are being made to Tonopah from the 100 and 175-ft. levels. The ore will be milled at Tonopah instead of being shipped to a smelter as was at first planned. The Syndicate is cross-cutting 50 ft. to the Arrowhead vein at a depth of 200 ft. The cross-cut is 25 ft. long. The Consolidated shaft is 200 ft. deep and a cross-cut is to be driven to the vein at 215 ft., or 100 ft. below the first level. Ore 12 ft. wide and assaying 15 to 20 oz. has been found in the west drift on the 115-ft. level and in the east drift there is 18 in. that can be shipped at a good profit. The Extension is cross-cutting to the vein at 150 ft. The Inspiration is to sink a new shaft. This company is now working through a 50-ft. shaft and a tunnel. The West Arrowhead shaft has entered a cross-vein at 100 ft. Sinking is being continued.

TULE CANYON.—The Silver Hills, operating the Ingalls mine under option, is building a 5-stamp cyanide mill, which, with the old plant, will give a total capacity of 50 tons daily. The average grade of ore being milled

is \$30 to \$35 and a saving of 80 to 90% is being made. The 100-ft. shaft has been re-timbered, the surface plant is in place and sinking will be started within a week. The Silver Hills is the only company working in the district. No work has been done in the placer field since early last fall.

VIRGINIA CITY.—The Paramount Mines Co. has been organized by Herbert Humphrey and associates to develop above the 1000-ft. level the Gould & Curry, Best & Belcher, and Savage. The opening of high-grade ore at 190 ft. by the South-west Comstock Extension, proving ore in this direction from the old producers, and the organization of the United Comstock Mines Co. to operate on a large scale near the surface of the Gold Hill mines has revived interest in the possibilities of the old mines and the surrounding section, and there are indications that the entrance of men with new plans of development will lead eventually to a big increase in the production of the noted old district that has been decidedly inactive during the period of low-priced silver.

DIVIDE.—Future work of the Tonopah Divide company will be supervised by G. H. Garry, consulting engineer for the Tonopah Belmont, and William Watters has resumed his former position as superintendent. The mine will be re-sampled. The shaft is 825 ft. deep and it is planned to continue sinking until the water-level is reached. A new 112-hp. hoist that lifts $3\frac{1}{2}$ tons 600 ft. per minute is now in use. The south-east drift on the 585-ft. level is 720 ft. long. The shoot of sulphide ore recently opened in this drift is "at least 26 ft. long" and has an average value of \$26, according to the last weekly report. The shoot has not been cross-cut. Several other Divide companies plan to sink shafts to not less than 1000 ft. The formation in most parts of the Divide district for several hundred feet from the surface is hard fine-grained rhyolite, the 'cap-rock', and tens of thousands of feet of work was done in this unfavorable formation during the boom, due largely to the anxiety of the managements to "start cross-cutting to the vein" because of the effect this had on the price of the stock. It has been proved that work in this formation was wasted and that the shafts must be sunk far into the rhyolite breccia before paying orebodies can be expected. Engineers think prospecting at 1000 ft. may have good results. The Dividend has started work at 800 ft. and the Brougher shaft is to be sunk to 1000. Among the companies planning to sink to 1000 ft. are the Sutherland and Rees, in the far northern part of the district.

GOLDFIELD.—The Development mill is ready to treat 100 tons of ore daily and shipments will be started from the Cracker Jack leases on the Florence and other sources of ore when the Interstate Commerce Commission approves the rate schedule of the Tonopah & Goldfield railroad for hauling. There has been found in the Cracker Jack lease, 40 ft. above the 500-ft. level, a 2-ft. width of ore assaying \$100. The shoot has been opened for a length of 30 feet.

UTAH

NEW ENGLAND MINE AT BINGHAM RESUMES OPERATIONS.

BINGHAM.—Operations at the New England mine will be resumed at once by a syndicate of Ohio, Pennsylvania, and New York men, who have taken over the property. The new company has been named the Utah-Boston Development Co., incorporated under the laws of Maine, for \$500,000. Purchase of the property was made for the syndicate by Robert M. Hampton, mining engineer of Tonopah, Nevada. The New England property was originally known as the Nast mine and had a production record of about \$550,000, which had been mined up to 1901, when the New England company purchased the mine. During the ownership of this latter company, production was increased to \$1,500,000, all of the ore having been mined from above a vertical depth of 200 ft. Since 1912 the property has been idle and the company involved in litigation. The property consists of approximately 50 acres of mineral ground, surrounded by the Utah Copper, United States Mining, and Utah Metal & Tunnel mines. Plans already made for the new company's operations provide for the development at depth of the already proved ore channels. The property is opened by a tunnel from which a shaft has been sunk. The shaft will be sent down an additional 500 ft., and a raise will be made in the shaft from the tunnel-level to the surface, giving a vertical depth of 800 ft. While the shaft is being sunk, production will be started from a known shoot of ore on the lowest level. Shipments made from this shoot in 1906 and 1907 are reported as averaging \$40 per ton, so with present metal prices, it will be considerably more valuable. Equipment on the property will be overhauled at once and new electrical hoisting equipment placed at the new shaft. A ten-drill compressor on the property will be repaired and started at once.

ALTA.—Shipments of ore from the Columbus Rexall property have been resumed. In the north end of the property, near the face of the main tunnel, it is estimated that there is 5000 tons of ore. Nearer the portal of the tunnel, in a raise, the company has 20 ft. of ore, which will not be taken out until square-sets arrive with which to mine it. The company has in its ore-bins, awaiting shipment, about \$25,000 worth of ore, while the 'ore in sight' is estimated at \$250,000. The holdings of the company in this camp total 112 acres, with an outstanding capitalization of 586,235 shares. The major portion of mining operations have been conducted at a vertical depth of 900 to 1000 ft., and at a distance of a mile from the portal of the tunnel. In addition to the adit, there are connections with the Frederick tunnel and with the 600 and 800-ft. levels of the Cardiff mine, affording ventilation and additional exits in cases of emergency. M. R. Evans states that operations will be conducted on a larger scale this summer than has been attempted heretofore.

PARK CITY.—According to rumors, the Judge Mining & Smelting, the Daly-West, and Daly Mining companies are considering the erection of a mill on the flats below

town. While officials of the companies have nothing to say, others in a position to know state that the plan is under advisement. All three of the properties have thousands of tons of milling ore, and it is probable that if such a mill were constructed, the Park Utah property would also join in the combination.

The Keystone property is reported as being in excellent condition. This mine is being worked through the Hanauer tunnel and the Kearns-Keith shaft. Before development work could be started, the tunnel had to be cleaned out for a distance of 1200 ft., and the shaft repaired for a distance of 250 ft. In a drift from the shaft, one of the big fissures of the district was cut and more than 20 ft. of good milling ore and considerable first-class ore opened. In a drift from the third level of the Columbia raise, several feet of exceptionally high-grade shipping ore, which carries gray copper and better than 100 oz. silver per ton, has been opened up. More than 500 tons of high-grade ore is stored in the bins at the mine, awaiting shipment. All of this ore came from prospecting work and no attempt has yet been made to stope any of the ore-shoots which have been opened. The roads in the vicinity of the Keystone are now getting in such shape that teams will be able to reach the ore-bins and operations at the property can be speeded up.

ETREKA.—The old water-line of the Eagle & Blue Bell Mining Co., extending from the company's wells at Homansville to the mine, is to be taken up, after having been in service nearly 30 years. The line is 7700 ft. long and contracts have been awarded for the uncovering of the old line and laying the new one. According to B. F. Fleiner, the Imperial Lead Co., in the West Tintie district, has been a steady producer for several months past; the ore being hauled by truck to Sugarville station on the Salt Lake Route. The Imperial Lead is owned by Salt Lake City interests. The mine has been a shipper for the past two or three years, but operations were not started on an extensive scale until late in 1919, with continuous production during the past winter and spring.

Recently the lessees who are at work at the old Sunbeam mine finished the job of re-timbering and cleaning out the shaft to a depth of 450 ft. This latter depth was the deepest point reached in the property when in operation some 20 years ago. E. R. Higgenson, mining operator of Salt Lake City, is in charge of the property and a total of 52 cars of ore has been shipped under his management. Recent smelter returns show the ore to be worth approximately \$50 per ton. Mr. Higgenson expects a better grade of ore when mining is resumed on the 450-ft. level.

BRITISH COLUMBIA

WORK RESUMED AT THE DOLLY VARDEN.

ALICE ARM.—A syndicate has been formed to explore and, if investigation proves satisfactory, to develop the Royal group of claims, adjoining the Dolly Varden mine. This property consists of seven claims held under a \$100,000 bond. It is conveniently situated as to transportation, a short aerial tramway being all that would be neces-

sary to connect it with the Dolly Varden railway. A settlement of the strike of employees of the Dolly Varden has been effected. It is stated that practically all the demands of the men were granted. Mines will be paid at the rate of \$6.25 per day; muckers, \$5.75; and trackmen, \$5.75. The union scale also will apply to cooks, mechanics, and other employees.

QUEEN CHARLOTTE ISLANDS.—George Clothier, Government mining engineer, has just finished an examination

MAP OF SOUTH-WESTERN BRITISH COLUMBIA

of some prospects of the Queen Charlotte Islands. He went over a free-milling gold property situated near Skidegate on the west coast of Moresby island and states that further development is warranted. The Ikeda mine near Jedway is to be opened up this season and it is reported that a concentrator is to be built. Quantities of high-grade copper ore have been shipped at various times and there now is a good deal of comparatively low-grade ore on the dump which, if facilities were available at the mine, might be treated at a profit. Surface work is

being done on the South Fork mine in the same section and another property near Delway is being inspected and reported upon by representatives of the American Smelting & Refining Co.

NELSON.—The McAllister mine at Three Forks is under development with promising prospects. R. A. Grimes, manager, states that the Slocan strike did not close down the work he has under way. This mine may be expected to join the shippers of the silver-zone of British Columbia at an early date. Some first-class ore has been uncovered and those interested are so well satisfied with the outlook as to be considering the purchase of further plant.

PRINCETON.—Preparations for the commencement of operations at Copper Mountain by the Canada Copper Corporation are well advanced. Trains already are running between Princeton and Allenby on the Copper Mountain branch of the Kettle Valley railway. The concentrator has been completed and awaits the power which is being brought over a high-tension line from Bonington Falls by the East Kootenay Power & Light Co. A large brick power-station has been constructed. H. R. Van Wagenen, general manager, has returned and it is expected that the mine and mill will start work in September.

ROSSLAND.—The Velvet mine, situated near Rossland, is being re-opened by H. E. Innis, of Sandon. Some months ago it was taken over by the Granby Consolidated Mining & Smelting Co. and the mine was unwatered and worked for a short time. The company, however, ceased operations. It is well equipped and, if Mr. Innis is successful in making it a producer, should become a valuable addition to the shippers of the camp.

VANCOUVER.—R. F. M. Sylvester has retired from the management of the Granby Consolidated Mining, Smelting & Power Co.'s interests in British Columbia, after ten years service in that capacity. Mr. Sylvester has developed the Hidden Creek mines with their ore-reserve of more than 11,000,000 tons, established the smelting plant at Anyox, developed and equipped the Cassidy colliery, and erected the by-product coke-ovens at Anyox. It is understood that his policy of expansion in the way of acquiring and developing other properties was not approved by some of the New York directors, hence his retirement.

ONTARIO

DISCOVERIES AT BEAVER HOUSE LAKE.

PORCUPINE.—Advance information as to the annual report of the Dome Mines for the year ended March 31 places the net profit at approximately \$650,000, after liberal allowances have been made for 'deferred development' and depreciation. It is stated that the mill-heads averaged \$6.50 per ton and that operating costs were between \$3.50 and \$3.60 per ton.

KIRKLAND LAKE.—The downward continuation of the orebodies found on the 300-ft. level of the Ontario Kirkland has been proved, assays of ore from the 450-ft. level showing gold content of \$16 per ton. The company has

contracted for the construction of a mill, the size of which will be determined by the results of further development. Development work has been resumed at the Granby-Kirkland, where the shaft on No. 1 is down 18 ft., the vein at that depth showing a width of 8 ft. At the Fidelity property the shaft is down 192 ft. It is being driven on an incline following the vein, which maintains its width. A small vein four inches wide has come in along the foot-wall side of the shaft.

BEAVER HOUSE LAKE.—Important discoveries of gold are reported to have been made on the south side of the lake about one mile from the Argonaut, causing a rush of prospectors and the staking of many claims in the locality. Recent developments at the Argonaut are of an encouraging character.

TORONTO.—The alleged inadequacy of the taxes paid to the Province by the International Nickel Co. has been the subject of frequent attacks on the Provincial government, which were renewed by the Liberal opposition during the session just closed. While apparently satisfied with present conditions, the assailants contended that the arrangement made by the former government under which the company paid a flat rate of \$40,000 per year for the years 1911 and 1915 was illegal, and that the Province was entitled to recover from the company the arrears of taxes properly payable for this period. A resolution introduced to that effect was withdrawn on a promise by Premier Drury that an investigation into the matter would be held.

COBALT.—Shipments of bullion have resumed normal proportions from Cobalt, although more than 1,000,000 oz. lies stored in the vaults at the leading mines. This is held on the strength of the belief that quotations for the metal will at least remain at the present level, with some likelihood of advances.

The Coniagas Mines has leased the cyanide equipment in the mill on the Buffalo company, and will treat approximately 40,000 tons of tailing which lies on the Coniagas close to the Buffalo boundary. The lease does not include the oil-flotation equipment in the Buffalo mill. Announcement is made that the Cobalt companies will continue to pay their employees a bonus of \$1.25 per day. The schedule of wages as agreed upon last fall amounts to \$3.50 for loaders and \$4 for machine-runners, plus a bonus of 25c. per day when silver averages 80c. per ounce, and an additional 25c. per day for each 10-point advance. During the early months of this year the price averaged above \$1.20 per ounce and the men received a daily bonus of \$1.25, making the wage and bonus total \$4.75 for loaders and \$5.25 for machine-runners. Now, however, with silver having declined to around \$1 per ounce the bonus would, according to the agreement, be reduced to 75c. The decision of the companies to continue to pay the higher rate is to relieve anxiety as regards the high cost of living, and to encourage miners to remain at their jobs. The \$1.25 bonus is guaranteed for at least six months, according to notices being posted at the mines.

ARIZONA

Tucson.—The engineering department of the University of Arizona has received sundry equipment, the gift of interested companies. The United Verde Copper Co. recently donated the following: One 6-hp. compound-wound 230-volt D. C. motor; two 31-hp. compound-wound 230-volt D. C. motors; three 31-hp. controllers. The John A. Roebling's Sons Co., of Trenton, N. J., builders of the Brooklyn bridge, have donated a handsome display board of electrical wires and cables of various kinds. The Inspiration Consolidated Copper Co. has given a 5-hp. D. C. motor.

Phoenix.—The Max-Delta Gold Mining Co. has purchased equipment for a 20-ton experimental mill.

CALIFORNIA

Amador County.—Sinking of the main shaft of the Central Eureka mine to a depth 150 ft. below the 3700-ft. level is progressing, and opening of a new level is to start shortly. The vein on the 3700-ft. level is showing the most uniform rich mill-ore opened for years, and monthly dividends are being disbursed. Unwatering of the Argonaut and Kennedy mines is proceeding at a good rate and will be finished earlier than originally anticipated, as it was found unnecessary to flood the property to as great a depth as first thought. However, it will be late in the fall before large-scale mining can be resumed.

Grass Valley.—The district is short about 300 miners as compared with June 1, 1919, according to careful estimates. High wages in other occupations and the summer call of the lumber-camps have drained considerable labor from the district. The North Star is now working on a reduced scale, but the Empire is managing to mine sufficient ore to keep its battery of eighty stamps in operation.—Rachel Benoit has sold three mining claims to the Grass Valley Consolidated Mining Co. The locations are quartz and known as the Modoc, Rising Sun, and Leader. The purchasers intend to operate them along with their other properties. The present wage-agreement between the miners and the operators will expire July 1 and committees appointed several weeks ago to draft a new scale are endeavoring to determine a satisfactory basis.

Shasta County.—The Shasta Zinc & Copper Co. has been organized to undertake further development of the property of the original Bully Hill Copper Mining & Smelting Co. The old smelter produced 40,000,000 lb. of copper, 2,000,000 oz. of silver, and 800,000 oz. of gold, the zinc being lost as oxide in the smoke. The Hayden-Stone and Jackling interests are joining Walter Arnstein and associates, who have had an option on the property for three years, in the new company. The metallurgical treatment has not yet been determined, but an electrolytic zinc plant in the vicinity of San Francisco bay is a possibility.

IDAHO

Boundary County.—The late spring has been advantageous to the Idaho-Continental, as it has conserved the water necessary for milling. Snow lies to a depth of two feet at the mine and to a greater depth on the hills above. No attempt to move ore will be made before July 15, when

the condition of the road is expected to become normal throughout its 26 miles between the mine and Porthill. The development of ore proceeded throughout the winter with a small crew, but since the resumption of milling the crew has been increased to 100 men in the mine and mill. The practice of the company is to operate the mill at capacity as long as water lasts, which is usually well into the fall, and in that period to accumulate a quantity of concentrate that may be hauled far into the winter.

Coeur d'Alene. The Consolidated Interstate-Callahan company, now the Callahan Zinc-Lead Co., shipped 15,974 tons of zinc and lead-silver ore and concentrate in the quarter ended March 31. The total net value of the product was \$591,691. After deducting all operating expenses and excess-profit taxes for 1920 there was a surplus of \$260,000, out of which the quarterly dividend of \$186,651, or 50c. per share, was paid.—Arrangements are complete for continuing the development of the Chicago Boston mine, at Wallace. Operations are proceeding on the 200-ft. level, where ore has been opened by a drift for 200 ft.—Ore from the Monarch mine is said to be the highest grade, with one exception, ever shipped from that section. It is expected to assay 60% lead and 8 oz. silver. Other shipments of 60% lead ore have been made and one went 72.5% lead.

Elk City.—The orebody, struck recently in the Grangeville mine of the Gold Zone company, is said to have been penetrated for 11 ft. without reaching the foot-wall. The find was made by tunnel at a depth of 200 feet.

Mackay.—A new find is reported in the deepest level of the Empire Copper Co.'s mine. The ore is heavy sulphide, assaying about 6% copper. The vein was entered during the night shift of May 27, and on June 1 the cross-cut was still in ore. In March 1919 the Empire company employed Morton Webber as consulting engineer. A glass model was made of the 18 miles of workings. With the information gained therefrom, in addition to a thorough examination of the mine, Mr. Webber advised the directors that the property was largely exhausted of available ore above the lowest level; but that development at depth should bring satisfactory results if properly carried out. Accordingly a new shaft was sunk and two new levels, No. 9 and 10, are now being developed. The new shaft will finally connect with a raise which will be driven from the Cossack tunnel. This will give the mine an additional 900 ft. of backs. The Empire Copper Co. has to date paid about \$1,000,000 in dividends and is the largest copper producer in Idaho.

MONTANA

Butte.—The Anaconda company has opened what is regarded as a large tonnage of high-grade ore below the 3700-ft. level in the course of the sinking of the Stewart shaft, the significant feature of the development being the grade of ore at this depth. This deposit assayed up to 40% copper with a large back available. If the shoot extends upward, as it is believed it does. The labor situation at Anaconda mines is not encouraging. In fact it is better in mines other than those owned by Anaconda. Considerable bitterness is manifest against the company, ore on the way to the smelter being found to contain chunks of iron, planned to disable the crushing machinery.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Albert Burch is at Bingham, Utah.

Horace V. Winchell was at Spokane last week.

Robert S. Lewis is at Huntington Lake, California.

Philip D. Wilson, geologist of Warren, Arizona, is at Vancouver, B. C.

William F. Staunton, of Los Angeles, was in San Francisco last week.

Harry D. Quibby, recently at Red Mountain, Colorado, is here on a short visit.

E. Hardy Smith is on his way from Korea to New York, by way of Vancouver.

H. C. Bollinger, consulting engineer to the Chile Copper Co., is visiting Spokane.

G. A. Swanquist has moved from Salvador, Central America, to Canon City, Colorado.

Frank R. Wicks is at Breckenridge, Colorado, on consulting work for the Royal Tiger Mining Co.

Orrin P. Peterson, of New York, is now with the Cia. Real del Monte y Pachuca, at Pachuca, Mexico.

E. Hogberg, of Kamloops, B. C., is now with the Amalgamated Gold Mines, at Blewett, Washington.

R. W. Stone, of the U. S. Geological Survey, is on his way to Miami, Arizona, where J. S. Diller is seriously ill.

J. C. Van Orsdel, president of the Mt. McKinley Gold Placers, with offices at Seattle, has moved the office to Kantishna, Alaska.

Gerald R. Lambert of Salt Lake City has accepted the position of associate professor of geology at the Montana State School of Mines.

H. J. Wasson, mining engineer in the geological department of the Marland Refinery Co., at Ponca City, Oklahoma, is at Riverside, Texas.

Walter Flitch, Jr., mining contractor of Eureka, Utah, is at the Prince Consolidated property at Pioche, inspecting work being done there.

J. Benton Leggat, general manager for the Argyle Silver Mining Co. at Basin, Montana, has returned to Salt Lake City after a visit to the property.

Solon Spiro, president of the Silver King Con. M. Co., at Park City, Utah, underwent a severe operation in New York on May 29. He is reported as improving.

Morton Webber, consulting engineer for the Empire Copper Co., is at the mines of the company at Mackay, Idaho. He will return to New York at the end of June.

E. P. Mathewson has been appointed consulting metallurgist to the Granby Con. M., S. & P. Co., and H. S. Munroe has been appointed manager to take the place of R. F. M. Sylvester, who has retired.

Obituary

William Lancaster, inspector of mines for the Kootenay district, British Columbia, was instantly killed in an automobile accident on May 29.

Edmund Gybbon Spilsbury, mining and metallurgical engineer of international reputation, died suddenly of heart failure on May 28, 1920, in New York after the operation for cataract had been performed upon his eyes a few days previous. He was president of the American Institute of Mining Engineers in 1896 and of the Engineers Club of New York in 1916 and 1917. He was also a member of the American Society of Civil Engineers, the American Society of Mechanical Engineers, the Institution of Mining and

Metallurgy, in Great Britain, the Mining and Metallurgical Society of America, the American Electrochemical Society, and the Rocky Mountain Club of New York. As the representative of one or another of the national engineering societies, he was a trustee of United Engineering Society from 1916 until his death; a member of Engineering Societies Library Board from its organization in 1913 until 1920, being its chairman from 1918 to January 1920; and a member of the Engineering Foundation Board from 1916 until his death. He was also a member of the Division of Engineering of the National Research Council. In all these societies and boards, he was an active and useful member, serving on numerous committees and contributing freely of his time and ability.

Born in London, England, in 1845, he attended school at Liège, Belgium, whither he went at an early age. His technical education was gained at the University of Louvain, in Belgium, where he was graduated in 1862. After leaving the University, he had a practical course at Clausthal, Germany. He came to the United States in 1870. His practice as a consulting mining engineer and metallurgist took him into many parts of Europe, Africa, the United States, Mexico, and South America. During the winter and early spring of 1920, he spent a number of weeks in Brazil on a mining project for clients in the United States and had returned to New York only a few weeks before his death.

In 1864 he entered the service of the Eschweiler Zinc Co., at Stolberg, one of the largest miners and smelters of lead and zinc in the world, as assistant engineer; in 1865 he took charge of that company's mines and works on the island of Sardinia; from Sardinia he went to the Atlas mountains, in Morocco. In 1867 he entered the service of McClean & Stillman, of London, and had charge of the construction of the iron gates for the Surrey Commercial Docks; in 1868 he was designing engineer with J. Casper Harkort and had charge of most of the detail work of the Keulenbergh bridge in Holland and the Danube bridge in Vienna, also the Rhine bridge at Dusseldorf. In 1870 he was again with the Eschweiler Corthalic Co. as chief engineer. In 1870 he was sent by the Austro-Belgian Metallurgical Co. to investigate the resources of the United States in lead and zinc. After spending two years in this work, he resigned in order to practise in the United States, where he was the first to introduce the Harz system of ore-dressing for the zinc ores of Pennsylvania and New Jersey. During this period he was engaged in explorations also on the northern shores of Lake Superior and in Colorado, Montana, Utah, and California.

In 1883 he became general manager of the Haile gold mine in South Carolina, and in 1887 he was engaged by Cooper, Hewitt & Co., of New York, and was managing director of the Trenton Iron Co., New Jersey, from 1888 to 1897. While manager of these works, he introduced as specialties of their business the Elliot locked-wire rope and the Bleichert system of aerial tramways.

In 1893 he presided over the sessions of the mining division of the International Engineering Congress at Chicago. He was the author of a number of important technical papers, among which may be mentioned 'Gold Mining in South Carolina', 1883; 'Chlorination of Gold-Bearing Sulphides', 1887; 'Improvements in Mining and Metallurgical Appliances During the Last Decade', 1897; 'Improvement in the Cyanide Process', 1910. In a lighter vein he wrote entertainingly. To the 'Mining and Scientific Press', in 1915, he contributed 'Technical Reminiscences'. Paragraphs from this narrative recall early interesting experiences and the notable progress in mining engineering during his half-century of active practice.

He is survived by three sons, Raymond G., Percifer G., and Hugh G., and by one daughter, Miss Beulah G., and a sister, Miss Matilda Spilsbury.—A. D. F.

THE METAL MARKET

METAL PRICES

San Francisco, June 8

Aluminum dust, cents per pound	65
Antimony, cents per pound	10
Copper, electrolytic, cents per pound	19
Lead, pig, cents per pound	8.75-9.75
Platinum, pure, per ounce	\$95
Platinum, 10% Iridium, per ounce	\$130
Quicksilver, per flask of 75 lb.	\$90
Spelter, cents per pound	8.50
Zinc dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

June 7.—Copper is dull but steady. Lead is inactive but firm. Zinc is quiet and a little stronger.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01½ on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.05 pence per ounce (925 fine) calculated at the normal rate of exchange.

MARKET PRICE OF SILVER DROPS TO 84c.

As we go to press the market price of silver in New York has dropped to 84c. per ounce in spite of the provisions of the Pittman Act. Information available is to the effect that a question has been raised by the Treasury officials as to the form of certificate prescribed for corporations or individuals offering silver for sale at the Mint. One phase of the question is the difficulty of positively identifying silver that has been in process at smelters and refineries for months, as having come from mines in the United States. It is hoped and expected that representations can be made to the Government officials that will adjust the difficulty, and permit the sale of all domestic silver at the rate of \$1 per ounce as provided in the Pittman Act. The following form shows the affidavit, concerning which question has arisen.

Certificate in Connection with Sale of Silver to Director of Mint

State of 192..
County of
In order to make a sale of silver to the Director of the Mint, in accordance with the provisions of the Pittman Act, approved April 24, 1918, the undersigned hereby represents and certifies, under oath, that he is the Manager of the owner of said silver, that said silver to the amount of fine ounces, delivered to the United States Mint at San Francisco, California, this day of 192.. for sale to the Director of the Mint under said Act, was produced in the United States at the (here insert name and location of mine, and dates), and was the product of reduction works situated in and that part of said silver was mined outside of the United States of America or at any time treated by reduction works or refineries located outside of the United States.

(Signature of vendor or duly authorized officer)
Subscribed to and sworn to before me this day of 192..
..... Notary Public.

State of
County of
The undersigned, being duly sworn, deposes and says that he has read the foregoing affidavit of dated 192.. and is the manager of the mine described in said affidavit; and that the silver described in said affidavit, in the amount of fine ounces, was produced in the United States at the said (insert name and location of mine, and dates).

(Signature of owner of mine or duly authorized officer)
Subscribed to and sworn to before me this day of 192..
..... Notary Public.

State of
County of
The undersigned, being duly sworn, deposes and says that he has read the foregoing affidavit of dated 192.. and is the manager of the mine described in said affidavit; and that the silver described in said affidavit, in the amount of fine ounces, was the product of said reduction works situated in in the United States and not the product of any reduction works located outside of the United States.

(Signature of owner of reduction works or duly authorized officer)
Subscribed to and sworn to before me this day of 192..
..... Notary Public.

Eastern Metal Market

New York, June 2.

A gradual improvement in the country-wide transportation conditions is apparent here and there in some of the markets, but the holiday recess from May 29 to 31 has interfered with any possible resumption of activity.

The copper market is inactive and firm, with demand light.

The tin market has been quiet with a recession in prices.

The lead situation is unchanged and prices are firm with a premium obtainable for spot delivery, New York.

There is still no life to the zinc market but prices are fairly steady.

Prices for antimony are lower.

IRON AND STEEL

Pig-iron production figures wired to 'The Iron Age' from all districts on the first day of June show a total for May of 2,988,881 gross tons. This is an average of 96,415 tons per day and compares with a total of 2,739,797 tons in April, or 91,327 tons per day. Thus there was a recovery of about 5000 tons per day from the slump in April to 17,000 tons per day below the March rate.

It is still the outstanding fact in the industry that output is best nearer the raw material end. While shipments of finished steel are again slightly better this week, the Pennsylvania Railroad leading in the improvement, pig-iron is picking up faster. Furnaces in blast on June 1 numbered 295, against 281 on May 1, and 312 on April 1. Resumption of a number of blast-furnaces is planned for the coming week.

A rapid return to normal railroad operation is now expected and as soon as adequate stores of fuel are collected an expansion of iron and steel-plant activity will ensue, following increased activity in the week in rolling-mills.

COPPER

This market is marking time. The acknowledged improvement in the transportation situation is having its effect in better supplies to refineries and in a more regular movement of finished material, but there is still no buying of consequence. Confidence is strong that a buying movement will set in soon since the technical phase of the market is strong in that production has been curtailed lately over 50% and stocks have declined. Against this, however, must be set the fact that melting by consumers has also lessened. But buying of copper appears in waves and as the last one was about two months ago it is figured that another is due soon. Producers generally are still maintaining their quotations at 19c., New York, for both electrolytic and Lake copper for June, and 19.25c. for July and perhaps August in some cases. In the outside market, which is decidedly limited as to scope, prices vary from 18.25 to 18.75c. for June. As to exports, it is probable that they were less in May than in any month this year. Inquiries from foreign sources are, however, good.

TIN

The market continues quiet, due partly to the holiday, but more largely to the fact that consumers appear to be discouraged with no ambition to buy. This is not strange in view of low prices. Tin fell last week to the lowest price in many months when it sold at 50c., New York, for spot Straits on May 27. The price has hovered around this level and up to 52c. since. Yesterday spot Straits was quoted at 51.50c., New York. Dealers also show a reluctance to buy and so transactions the past week have been light as compared with previous ones. The total for all positions and all grades, as made on the New York Metal Exchange, has been less than 150 tons at prices ranging from 49c. for

June delivery to 50.50c. for July delivery. Late last Thursday there was a fair demand for Eastern-shipment metal, mostly from dealers, at 50.75 to 51.25c. The London market was quoted at £287 5s. for spot Straits yesterday against £289 per ton a week ago. Arrivals of tin for May were 6230 tons, of which only 350 tons came in at Pacific ports. Deliveries of the metal into consumption in May were 3550 tons, with 5356 tons in stocks and landing on May 31. Total imports to June 1 were 23,013 tons against 6341 tons to June 1, 1919. Of the imports this year 18,420 tons has come from the Straits Settlements.

LEAD

The only point of interest in this quiet market is that spot lead, New York, is still available at 9.37½c., at which price also sales again have been made. But there is no urgent demand for it and buyers have lost more if not all of their anxiety. Deliveries are better from the West, indicating the gradual improvement in transportation. We quote the outside market unchanged at 8.15c., St. Louis, or 8.50c., New York, with that of the leading interest at 8.25c., St. Louis, and 8.50c., New York.

ZINC

The market continues devoid of any features. The most that can be said is that prices have not fallen further. Demand is very light, neither consumers nor sellers showing any interest in early delivery nor in futures. The London market was higher yesterday, and so was sterling exchange, which caused a slight advance in the price over last week. We quote prime Western for delivery in the next two months at 7.70c., St. Louis, and 8.05c., New York, with about 7.75c., St. Louis, and 8.10c., New York, asked for third quarter. The holiday recess has also been a factor here as in this and other markets.

ANTIMONY

This market is duller and lower. Wholesale lots of the lower grades for early delivery are quoted around 8.87½c., New York, duty paid, with the better grades commanding 9c.

ALUMINUM

The market is unchanged with the leading producer asking 33c., New York, for virgin metal, 98 to 99% pure, in wholesale lots for early delivery and other sellers quoting 31.50c.

ORES

Tungsten: There has been no change and the market is still inactive with prices largely nominal at \$6.50 to \$15 per unit, depending on the grade and the delivery. Not much is expected until the tariff matter is settled.

Ferro-tungsten is quoted at 85c. to \$1.15 per lb. of contained metal in the alloy or the powder.

Molybdenum: This market is dead and quotations are nominal at 75c. per lb. of MoS₃ in regular concentrate.

Manganese: There is a good demand for the ore at prices from 80c. to \$1 per unit, but not much is publicly offered.

Manganese-Iron Alloys: Quotations are unchanged and firm at \$250, delivered, for June and \$200 for last half, at which a few transactions are reported. The slackness in steel output has relieved the tension and accounts for the present quietness. There are now four companies making ferro-manganese in electric furnaces, the Anaconda company, the Southern Manganese Corporation, the Tennessee Manganese Co., and the Ferroalloy Co., Denver. Output from all sources in May was the largest for any month this year or over 24,500 tons. The spiegel-eisen output was over 12,500 tons in May, or the second largest for the year. The quotation is firm at \$75, furnace, and 300 tons has been sold to an Eastern consumer.

Company Reports

TONOPAH BELMONT DEVELOPMENT CO.

Report for the year ended December 31, 1919.

Property: mines and mill at Tonopah, Nevada, and interests in properties elsewhere.

Operating Officials: Frederick Bradshaw, general manager; L. R. Robins, mine superintendent; W. H. Royston, mill superintendent.

Financial Statement: value of production, \$1,231,482; net value of bullion, \$1,124,857; operating expense, \$742,861. Net earnings at Tonopah, \$381,995. Income from Belmont Surf Inlet mines, \$204,352. Net profit, \$569,807.

Dividends: during 1919, \$375,000; to date, \$10,013,063.

Development: 5282 ft. of work was done. The assured reserves amount to 112,133 tons as against 82,798 tons one year earlier.

Production: during the year the mill treated 133,332 dry tons of ore, of an average metal content of 0.141 oz. gold and 13.54 oz. silver and an average per-ton value of \$17.889. The aggregate metal content of the ore was 18,834 oz. of gold and 1,804,951 oz. of silver, and the total money value was \$2,385,248. There was recovered as bullion 16,960 oz. of gold and 1,533,042 oz. of silver, and in concentrates and by-products, 857 oz. of gold and 117,627 oz. of silver.

UNITED EASTERN MINING CO.

Report for the year ended December 31, 1919.

Property: mines and mill at Oatman, Arizona.

Operating Officials: J. A. Burgess, general manager; W. O. North, assistant general manager; D. B. Boalen, mine-foreman; Earl M. Bagley, mill-foreman.

Financial Statement: gross value of ore milled, \$2,031,594; loss in tailing, \$61,085; recovery, \$1,970,509; operating cost, \$883,836; net income from operations, \$1,073,935. Current assets on December 31, \$826,666.

Dividends: during 1919, \$899,589; total to date, \$2,153,540.

Development: work for the year amounted to 3730 ft. at the United Eastern and 350 ft. at the Big Jim mine. In addition to this 769 ft. of raising was done to furnish ventilation and passes for slope-billing. Drifting on the seventh level has exposed the main ore-shoot for a continuous length of 750 ft. and the face of the south drift, which is now being driven, shows ore of milling grade 7 ft. wide. Development work is being extended laterally. The estimate of assured ore-reserves as of January 1, 1920, is 269,207 tons having a gross value of \$6,000,820 and an average of \$22.29 per ton, as compared with estimate of assured ore-reserves as of January 1, 1919, of 265,363 tons having a gross value of \$6,467,005.

Production: 97,325 tons of ore was milled; 91,264 oz. of gold and 55,974 oz. of silver were recovered. Value of ore per ton, \$20.87; average price of silver, \$1.13.

BUTTE & SUPERIOR MINING CO.

¹ Report for the year ending December 31, 1919.

Property: mine and mill at Butte, Montana.

Operating Officials: Charles Bocking, general manager; E. V. Daveler, general superintendent; Angus McLeod, mine superintendent.

Financial Statement: operating revenue, \$5,912,640; less freight, \$1,051,471; net, \$4,861,169. Operating costs, \$3,944,897; net income plus depletion, \$916,272. Balance on December 31, 1918, \$5,698,654; paid in settlement of Elm Orlu litigation, \$2,719,778. Surplus on December 31, 1919, \$3,062,121.

Dividends: none during 1919; total to date, \$16,940,258.

Development: there was performed during the year, 11,879 ft. of drifting, 6448 ft. of cross-cutting, 2699 ft. of

raises and winzes, and 43 ft. of stations, or a total of 21,099 ft., exclusive of 1793 ft. of diamond-drilling. The estimate of ore-reserves as of December 31, 1919, shows 624,300 tons averaging 16 7/8% zinc and 5.7 oz. silver as compared with the estimate of 830,000 tons at December 31, 1918, averaging 17% zinc and 5.7 oz. silver. The decrease is accounted for partly by the consent decree in apex litigation with the owners of the Elm Orlu claim, whereby a considerable tonnage of developed ore was lost.

Production: the total ore milled for the year was 403,436 tons, of an average grade of 14.698% zinc and 6.25 oz. silver. The mill recovery for the year averaged 95.528% of the zinc contents. The direct milling cost for the year was \$2.71 per ton, as compared with \$2.92 for the preceding year, a decrease of 18c per ton. The zinc concentrate contained 2,521,414 oz. of silver, 10,874,039 lb. of lead, and 118,591,220 lb. of zinc, and the lead concentrate contained 12,293 oz. of silver, 1,587,018 lb. of lead, and 329,853 lb. of zinc.

TONOPAH EXTENSION MINING CO.

Report for the fiscal year ended March 31, 1920.

Property: mines and mill at Tonopah, Nevada.

Operating Official: John G. Kirchen, general manager.

Financial Statement: net income from sale of bullion, \$1,056,754. Cost of mining, \$385,898; cost of milling, \$280,702; other costs, \$74,797. Net income, \$346,653. Current assets, \$1,061,196.

Dividends: during fiscal year, \$321,178; total to date, \$2,361,379.

Development: 5941 ft. of work was done during the year in addition to 595 ft. of diamond-drilling. Several branches of the Murray vein, which were good producers on the 1680-ft. level, remain to be developed on this level. Preparations have been made to sink the Victor shaft 150 ft. deeper and establish a level at the 1880-ft. point. Due to the shortage of miners, this work was not undertaken.

Production: there was mined during the year 70,611 tons of ore, all of which was treated. The gold and silver content of this ore was as follows: \$88,411 oz. silver, an average of 12.157 per ton; \$186 oz. gold, an average of 0.116 oz. per ton. These figures show a decrease, as compared with last year, of 0.661 oz. of silver and 0.005 oz. of gold per ton. The average price received for silver was \$1.1744 per ounce, and \$20.6718 per ounce for gold, making the average gross value of the ore mined and milled \$16.676 per ton, of which \$14.278 was silver and \$2.398 was gold.

BENKER HILL & SULLIVAN MINING & CONCENTRATING CO.

Report for the year ended December 31, 1919.

Property: mines, mills, and smelter at Kellogg, Idaho.

Operating Officials: Stanley A. Easton, manager; R. S. Handy, mill superintendent; M. H. Sullivan, smelter superintendent.

Financial Statement: gross lead and silver value of product shipped, \$4,990,731; dividends from Caledonia and Sierra Nevada companies, \$234,065. Total operating profit, \$1,888,559. Depletion and depreciation charged off, \$1,630,042.

Dividends: during 1919, \$1,144,500; total to date, \$23,803,500.

Development: conditions made the usual development impossible during the year; but the moderate amount of such work conducted on No. 15 level, the bottom level of the mine, was extraordinarily successful. The extension of the mine workings in the Stenwinder and Sullivan mines has also exposed additional ore.

Production: 393,698 tons of ore was concentrated, in addition to 86,925 tons of tailing; 80,002,268 lb. of lead and 1,375,657 oz. of silver were produced from the mine.

Book Reviews

Mechanical Drafting Manual. By Charles B. Howe. Part 1. General Principles of Drafting and Working-Drawings. Part II. Geometry of Drawing. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, 50 cents each.

These are evidently for use in the class-room or elsewhere in connection with the author's 'Mechanical Drafting'. They could hardly be used to advantage in any other way. Each 'Part' consists of a heavy envelope containing about fifteen 6 by 8 in. sheets, upon each of which are directions and sketches for the performance of a particular lesson in the subjects indicated by the titles above. This particular form is unusual for an instruction course, but there are certain evident advantages.

Topographic Maps and Sketch Mapping. By J. K. Finch. Pp. 170, ill., index. John Wiley & Sons, Inc., New York. For sale by 'Mining and Scientific Press'. Price, \$2.50.

Interest in maps, and particularly topographic maps, has been stimulated, like interest in so many other subjects, by the War. The treatment in the present volume is non-technical and can be followed readily by the layman who has only the most elementary knowledge of mathematics. The book will be useful principally to two general classes of readers; first, men and women that use topographic maps but who do not know how to get the maximum benefit from them, and second, students engaged in learning to make a map that will be of maximum benefit to the user. The book is therefore appropriately divided into two main parts, Map Reading, and Sketch Mapping, besides a short additional chapter on Landscape Sketching. The discussion of map reading covers three chapters entitled, respectively, What a Topographic Map Shows, How to Get Certain Information from a Map, and Use of Topographic Maps in the Field. Part II, on Sketch Mapping, is similarly divided into Topographic Drafting, Flat Mapping, and Contour Mapping. The appendix contains a descriptive list of the principal topographic maps of the world, suggestions for a course in map reading and sketch mapping, and a bibliography, the first of the three divisions being particularly valuable.

Prospector's Field-Book and Guide. By H. S. Osborn. Ninth edition, revised and enlarged by M. W. von Bernewitz. Pp. 364, ill., index. Henry Carey Baird & Co., New York. For sale by 'Mining and Scientific Press'. Price, \$3.

Mr. von Bernewitz has drawn largely on his diversified experience in New Zealand, Australia, and the United States in his revision of this work. The introduction contains many hints for prospectors and others interested in mining. There are 16 chapters devoted to preparatory instruction, the blow-pipe, crystallography, surveying, analysis of ores, gold, silver, platinum, copper, lead, zinc, antimony, iron, chromium, manganese, molybdenum, titanium, tungsten, uranium, vanadium, tin, mercury, bismuth, nickel, cobalt, cadmium, aluminum, petroleum, asphalt, oil shale, ozokerite, various useful minerals, abrasives, gem stones, useful rocks, and weights and measures. Much new material has been included, among the noteworthy additions being lists of equipment for a prospecting outfit, data on field-tests, notes on sampling, an explanation of the unit system of selling ore, an entirely new section on alloy minerals, and numerous new illustrations. The chapter on oil has been expanded and the discussion of oil-shale is a new feature. The index and glossary are exceptionally practical. Aside from the information which the prospector in the field may find in the volume there is material of value to the engineer, and others interested in mining from a practical or a technical stand-

point. The book is of pocket size and has a flexible cover which adds to its convenience.

The New Industrial Unrest. By Ray Stannard Baker. Pp. 231. Doubleday, Page & Co., Garden City, New York. For sale by 'Mining and Scientific Press'. Price, \$2.

The author of this book is well known to the reader of popular magazines because of his articles on both industrial and political matters. He approaches the field of industry from the standpoint of an outside investigator, but, nevertheless, an investigator who is honestly desirous of learning the truth and of being fair to both sides. The first few chapters are devoted mainly to the steel strike. While admitting the excellence of the welfare work done by the U. S. Steel Corporation, and the sincerity and good intentions of the officials both before and during the strike, he holds that the Corporation is an industrial autocracy, and considers Judge Gary as typical of the ultra-conservative employer. Both employers and workingmen he divides into three general classes: conservatives, moderates, and radicals, and considers that the moderates in both groups are still in the majority. He discusses various solutions offered by the two sides for the problem of unrest, and places his own approval on some form of works-council system. In particular he discusses the application of this system to the men's clothing industry. Considerable space is also devoted to employment management as a means of helping in obtaining better industrial relations. In the endeavor to be timely and up to date, the author has perhaps erred on the side of too hasty composition, but the book will be read with profit by many people that could not be induced to look at some of the more scholarly studies of industrial relations.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

FROM THE MINING OF THE ORE TO THE FINISHED PRODUCT

The completion by the Anaconda Copper Mining Co. in 1918 of a rod and wire-drawing mill at Great Falls, Montana, marks a new departure in the industry in that the company now manufactures the copper that it produces into copper wire, strand, trolley-wire, and rolled-copper rods. The addition of this final step to the long process of mining, concentrating, smelting, and refining, is of great advantage to the users of the products, for the direct supervision from the mining of the ore to the finished product, assures a product of unvarying high quality.

The ore mined at Butte, containing about 3% copper, is first enriched to 8% by concentration. The fine concentrate

are made. The finished cathode is 38 by 30.5 in. and weighs 130 lb.; 160 tanks of cathodes are drawn daily and 40 tanks of anodes are changed each day.

The slime contains approximately 12,000 oz. silver and 75 oz. gold per ton. The following is a typical analysis of the electrolyte in the refining tanks.

	Gm. per litre
Free acid	180.0
Copper	43.0
Arsenic	7.0
Antimony	0.5
Chlorine	0.035

The electrolyte has an average specific gravity of 1.235; its purity is maintained by running off daily to the purification

The Anaconda Company's Plant at Great Falls

is then roasted to remove 80% of its sulphur, and is then smelted in reverberatory furnaces; the coarser ore goes to the blast-furnaces. The reverberatory and blast-furnaces produce matte, (40 to 50% copper), and slag as a waste product. The matte is treated in converters which deliver an impure copper. The last stage is reached in the refining furnaces which turn out commercially pure copper, which is cast in the shape of anodes and shipped to Great Falls, Montana, and Perth Amboy, New Jersey. The anodes contain approximately 70 oz. silver and 0.25 oz. gold per ton.

The new electrolytic copper-refinery at Great Falls, which began operation in March 1918, contains 1020 refining tanks, 60 of which are devoted to the production of starting sheets. The tanks are divided into eight sections of 120 each, and are arranged in cascades of five. A separate electrolyte is maintained for each section, and it is pumped by means of air-lifts. The anodes used are of the lug type, 36.5 in. long and 28 in. wide. They are handled by means of a narrow-gauge railway. These cars are moved into the tank-house where the crane transfers 25 anodes at a time from the car to the refining tank. Each tank contains 25 anodes and 26 cathodes. The anodes remain in the tank 24 days during which time four drawings of six-day cathodes

tion plant a sufficient amount of solution to prevent building up. In the purification plant, the solution is concentrated by boiling to 48°B. and run to crystallizing tanks, where about 8% of the copper is recovered as bluestone; the remainder is drawn off and treated in anode-tanks for the removal of the remainder of the copper and the arsenic, antimony, and bismuth. The outlet solution from these tanks is further concentrated by boiling to 56°B. After cooling the iron, nickel, lime, and magnesia are precipitated as basic salts. The bluestone is re-dissolved and returned to the tank-room.

The copper as it comes from the electrolytic refinery is nearly pure but before being shipped to the consumer must be melted and cast into shapes suitable for rolling mills or manufacturers of brass and other alloys. This part of the process is carried out in the furnace refinery. The furnace refinery is equipped with two reverberatory copper-refining furnaces, each with capacity for melting 400,000 lb. of copper day. Each furnace is provided with a casting wheel, mold-presses, and other necessary apparatus for economical handling of the product.

The cathodes are delivered to the furnace-refinery on industrial cars, each car carrying four piles of cathodes, the

load weighing about eight tons. When a furnace is to be charged the three large charging doors on the side of the furnace are opened. The charging crane is brought into position in front of the furnace. The long arm on the crane picks a pile of cathodes from the car, thrusts it into the furnace and deposits it. It requires three hours to bring the furnace up to a melting temperature which is from 1100 to 1300 C. About eight hours after the furnace has reached this temperature the charge has all been melted and is free from the furnace-bottom. The slag that has formed, consisting mostly of copper oxide, is now skimmed off, leaving the bath clean.

The refining process is designed to get rid of the absorbed gases in order that physically sound castings may be made. In order to bring this about iron pipes are thrust into the bath of molten metal, through which air is blown. The oxygen of the air unites with the copper, forming cuprous oxide in the presence of which the gas ceases to be soluble in the metal and is expelled. It is rarely necessary to carry the oxidation beyond this point. In this process the impurities contained in the metal are oxidized, and hydrogen, carbon monoxide, and sulphur compounds are driven off.

After oxidation has been completed large wooden poles are thrust into the metal bath and held down beneath the surface of the metal. The dry distillation of the wood tends to reduce the cuprous oxide with which the bath of metal is now saturated. This operation is continued until the oxygen has been reduced to about 0.060%. At this point the polling is discontinued and the slag is skimmed. The bath is now covered with charcoal, and the polling resumed. The polling operation causes agitation of the metal, bringing all of the metal in contact with the charcoal covering the bath. When the copper contains from 0.010 to 0.025% oxygen, it is ready to cast.

The tap hole, launders, and ladles have by this time been made ready for tapping. The wall of refractory material at the tap-hole is cut away, and the metal overflows and passes through a Y-shaped launder into the ladles, of which there are two for each machine. The casting wheel itself is 40 ft. in diameter.

As the molds move around the circle they are sprayed both from above and below to promote cooling and after they have passed half-way round the circle are automatically dumped, allowing the castings to fall into a bosh filled with water. It is this chilling in water that gives the castings or shapes their characteristic red color. The metal when ready for shipment has the following approximate analysis:

	%
Copper	99.96
Oxygen	0.03
Silver	0.0022
Bismuth	0.0004
Sulphur	0.002
Iron	0.0006
Cobalt and nickel	0.0006
Arsenic	0.0017
Antimony	0.0016
Selenium	0.0009

Slag from furnace operation is re-smelted either in the blast-furnaces or converters. The building for the rolling mills is 450 ft. long by 125 ft. wide and is constructed of steel, brick, and glass. The rod mill consists of an 18-in. roughing mill, intermediate mill, finishing mill, bar-heating furnace, coilers, roll-lathe for grooving the rolls, and other accessory apparatus necessary to make the mill complete. The wire-drawing machinery, consisting of a 4-block bench for drawing large sizes of wire in coils; a continuous trolley-wire drawing-bench with its reel-stand; one 10-die and one 9-die continuous, double block, wire-drawing machine for drawing No. 12 and smaller sizes of wire, in coils or on reels; two 6-die and one 5-die double block machines for

drawing wire from No. 6 to No. 12, and three single-die machines for drawing medium hard wire. The annealing equipment consists of one double chamber non-oxidizing annealing furnace and one open-fire furnace. The stranding equipment consists of four stranding machines of different capacities. All of these machines are served by a 5-ton traveling crane, which covers the full width of the building and runs its entire length.

It is interesting to note that the products of the rolling-mills department are the first of their kind to be manufactured west of the Mississippi. Previous to the erection of this plant, the wire bars from the furnace-refinery were all shipped to mills in the East and Middle West. When wire and strand were required for the power-development projects in the West it had to be shipped back.

LINK-BELT 'LETTGO' MECHANICAL OVERLOAD-RELEASE

An effective safety-first device that will instantly disengage a drive when the load exceeds a predetermined point, has been developed by the Link-Belt Co. It is known as the 'Lettgo' mechanical overload-release. It is especially adaptable for elevating, conveying, and power-transmission machinery. The 'Lettgo' will automatically disengage the driving from the driven machinery if the load exceeds the fixed amount, thus allowing the driving motor or other source of power to run free and prevent damage, due to the inertia of the motor armature or other high-speed moving parts.

The construction of this device is such that it will release whether the load is gradually or suddenly applied, but it can be set so that it will not trip from jars or shocks. The device is symmetrical, and can be assembled to operate in either direction. It can be adjusted for tension, so that it will operate for any desired overload. The mechanism is entirely enclosed and can be packed with grease for lubrication purposes. Being positive in its action and easily reset, the Link-Belt 'Lettgo' has distinct advantages over other devices designed to accomplish the same result.

COMMERCIAL PARAGRAPHS

The report of the trustees of the pension fund of the Fairbanks-Morse Co., for 1919 shows eight members pensioned, death benefits of \$11,675, and net resources of \$505,000 practically all invested in high-grade bonds. The fund was established on January 1, 1917, and at the close of 1919 had 1139 contributing members.

The folder entitled 'Recent Notable Achievements', which was included in the annual stockholders' report of the Westinghouse Electric & Manufacturing Co., East Pittsburgh, Pa., tells about the work of the company in supplying electric locomotives to the Chicago, Milwaukee & St. Paul railroad; the electric equipment of the battleship 'Tennessee', and other naval vessels; and the 70,000-kw. steam-turbine in the 74th Street station of the Interborough Rapid Transit Co. Some of the large steam-turbine plants now in progress of construction are listed.

The Worthington Pump & Machinery Corporation, 115 Broadway, New York, announces to the engineering profession and to the trade that, in addition to the well-known lines of hydraulic machinery which it has manufactured since 1840, it has now completed preparations to furnish improved waterpower machinery of all capacities for low, medium, and high-head service, including oil-pressure systems, water-wheel governors, and other auxiliaries. It is entering this field equipped to produce hydraulic turbines to meet the highest standards in design, efficiency, and workmanship. To supplement its experienced staff, familiar with hydraulic problems, it has secured the services of competent designers having many years of successful experience. The hydraulic-turbine department is prepared to receive inquiries, which will be given prompt and careful attention.

T. A. RICKARD, . . . Editor

THE American Institute of Mining and Metallurgical Engineers will meet from August 20 to September 3 in the Lake Superior region. Sessions will be held at Iron Mountain and Hibbing.

MINE-FOREMEN and shift-bosses are disinclined to take kindly to direction from young and inexperienced mining-school men. On the other hand, many of these young graduates over-estimate their own wisdom and fail to give due consideration to the practical man who may know more about his own mine than he can well put into words. In an article on another page Mr. Paul Billingsley describes the relations between the staff of young geologists in the employ of the Anaconda Copper Mining Company and the superintendents and foremen of the 25 mines operated by the company in Montana. According to his idea, a reasonable amount of "humbleness in spirit" in the attitude of young geologists is one of the chief factors in promoting co-operation. Other features of the work of the geological department are emphasized by Mr. Billingsley in an interesting way.

A GENIUS from Hanford, California, the father of "over thirty inventions, one of which has been patented", announces the perfection of a set of "scientific, accurate, and practical instruments" that should make prospecting not only definitely successful, but delightfully easy and comfortable, and unattended with the hardships usually experienced by the seeker for nature's hidden treasure. In apprising the "interested public" of its good fortune in having available his services and instruments, the inventor makes this startling assertion: "That they will locate or indicate the whereabouts of a mineral or ore vein, and buried treasure, while riding at full speed in an auto, and that distance does not seem to make any difference in their locating power. I have tested some of my instruments for a distance of over 350 miles." We marvel at the velocity, but we can readily accept the statement in so far as it describes the uniformity of results. In these days of gloom, it is pleasant to contemplate anything cheerful, even a cheerful liar. Taking the inventor's own conservative figures, there are alluring possibilities in a range of operation circumscribed by a 350-mile radius. The would-be mine-owner could prospect the entire Rocky Mountain region in the course of a fortnight without ever emerging from the

comfortable corner of a pullman car. Here is a further assurance: "I have perfected separate instruments to locate the following minerals: gold, silver, copper, lead, galena, magnesite, molybdenum, chromite, zinc, nickel, cinnabar, tungsten, platinum, and oil." The presence in the list of a 'galena detector' as well as a device for lead reminds one of the farmer who, after the cat had kittens, cut a small hole in the floor of the corn-crib, beside the large one by which the mother was wont to enter. Unfortunately, "Germany is the only country that will patent mineral instruments, hence I do not sell or loan these instruments, but only locate with them upon the following terms". For "locating a mineral vein or lode" these terms are "\$15 per day plus traveling expenses, and half of what is located". However, special rates will be arranged when more than one location is made for a single client, so that a sizable enterprise can avail itself of the services of this scientific prospector without pledging 50% of its future production. This seems only fair. The gentleman belongs to a genus with which we can claim some acquaintance already. There be those who can diagnose the geology of a region by aid of a telescope; there are others who can appraise a mine from a specimen of ore; there are scribes who can write articles on mining districts without going to them and give wordy accounts of processes without seeing them in operation; the world is full of fakers, a word that must not be confused with 'fakir'. A 'faker' is one who makes or contrives; it is a good Anglo-Saxon word. 'Fakir' is Arabic for poor man and designates the mendicants or religious beggars of the East. Some of these fiscal agents, as they are called in the vernacular of today, are something of both; they concoct, they beg, and they almost make a religion of the art of deception.

THIS year the Republican nomination for the presidency is of more than usual significance because every well-informed person knows that the nomination is very nearly equivalent to election. Viewing the nomination made at Chicago from a non-partisan standpoint we confess that we would have preferred the ticket to be Coolidge and Harding; but this is a great year for the political machine; it ironed out the Hoover campaign in California and it went over the Chicago convention with a result that is decidedly flat. Under the circumstances it is fortunate that a politician so respectable and acceptable as the senator from Ohio should have been nomi-

nated. He belongs to the same class as McKinley. Two men, at least, of real intellectual power were set aside deliberately; we refer to Mr. Herbert Hoover and Mr. Nicholas Murray Butler; but they are not politicians, and to be President one must be a politician as well as a statesman. That is the consequence of our system of selection. Moreover, the presidency is not only an administrative but also a political office; the President is the head of the dominant party, and his co-operation with Congress is essential to the efficiency of the Government. Unusual gifts of mind, without the political sense, have brought disaster to the present holder of the office. The clash of interests and the conflict of ideas in a republic such as ours call for sympathy as well as imagination, for understanding as well as knowledge. The Democratic opportunity is larger than it seemed before June 12, but it is unlikely that it will overcome the disability of being identified with the outgoing Administration.

The Supply of Oil

We note that the Federal Trade Commission has investigated this subject, at the request of Congress, and has issued a report that seems to us to be just and reasonable. The Commission concludes that the increase in the price of petroleum products is due rather "to varying conditions of supply and demand in the light of emphasized and pessimistic statements as to a future supply than to a combination in restraint of trade". Healthy competitive conditions still obtain in the oil industry, it is said. The recent advance is due primarily to interruption in transportation, as well as to the increase in consumption. On the whole, the Commission considers that "the psychological factors in the situation were more important than the actual statistical condition, the mental attitude of the oil trade being strongly affected on the one hand by the frequent statement that there was an impending decline of production in the United States, which was aggravated by the sudden slump of North Texas output in the middle of 1919, and by the unfavorable development industrially and politically in Mexico in the autumn of that year". To this state of mind the addresses and other published statements of the directors of the U. S. Bureau of Mines and Geological Survey have contributed largely, for both of these authorities have struck a note of panic in regard to the proximate exhaustion of our domestic oil resources. The Commission makes two sensible suggestions, the first is to encourage American enterprise in the production of oil in foreign countries, and the second is to restrict the exportation of our own oil. Here it is only right to note that Mr. Franklin K. Lane, in his annual report as Secretary of the Interior, stated that "the encouragement of, and effective assistance to, our nationals in developing foreign fields is essential to securing the oil needed". In this connection we submit that it is ridiculous to criticize the British for developing oil resources abroad, when, in the first place, the British dominions have only 2½% of the world's production of petroleum, while we have 70% of

it in our own country, besides the control of 12% more, in Mexico, Rumania, and South America. Let us emulate their enterprise and 'go after' the oil that is obtainable in countries willing to permit our nationals to exploit their resources, and let it be the business of the Administration at Washington to support and protect our nationals in their legitimate enterprise abroad. Next, it is absurd to exclaim against the high price of oil while we allow the domestic market to be depleted by exportation to foreign countries. On this phase of the subject the politicians are silent because they are afraid to tread on the corns of what are called the big interests, but it is manifest insincerity to assist Irish propaganda by attacking the legitimate enterprise of the British while we are so careless about our domestic supply as to allow it to go to Australia and to other British dominions. During the month of April there was exported through the port of San Francisco 40,267,230 gallons of oil valued at \$2,556,208, of which 867,628 gallons, worth \$273,413, was gasoline. It matters much less who produces the oil than who receives it, that is, into which market it goes. If Americans produce oil in Burma and it goes to London, it helps us no more than it helps the British if a British company produces oil in California and sells it in San Francisco or New York. Let us keep our own production for our own use and then let us go abroad to obtain the further supply that we may need. In any event, we do not suppose for a moment that gasoline derived from petroleum will be the motor-spirit of ten years hence; by that time we shall be using some derivative from coal or some form of alcohol. Besides, we have tremendous resources in our oil-shale deposits. Meanwhile let us adopt a straightforward enterprising policy worthy of a great pioneering people and go into the waste places of the earth for all the oil or other mineral products that we may need, not sit around belly-aching about the self-interested explorations of other people.

The Collapse of Silver

On our financial page last week we recorded the fact that the price of silver on the open market in New York had declined to 84 cents; at the same time we printed the form of a three-fold affidavit that the Director of the Mint requires from the vendor, from the mine-owner or producer, and from the manager of the reduction plant at which was refined the silver in any bullion offered for sale at the Mint. Consignments of bullion accompanied by this affidavit, duly acknowledged, have at no time been declined by the officials of the Mint, but, on the contrary, have been accepted and paid for at \$1 per ounce in accordance with the provisions of the Pittman Act. Unless the Act be repealed this will continue to be done until at least 207 millions shall have been purchased. On the other hand, producers of silver-bearing ore have found that in their settlements with the smelters the New York quotation, which, as stated, touched 84 cents on June 8, has governed, in accord with the contracts under which the ore was sold. Many have been unable to reconcile these apparently conflicting prices and have felt

that they were not being fairly treated. The explanation is not difficult. Under the terms of the Pittman Act, the silver purchased at \$1 must be the product both of mines situated in the United States and of reduction works or refineries so situated, and clear and unequivocal proof to this effect must be supplied. As will appear from a perusal of the form of the affidavits, which we printed last week, this proof must be furnished for each individual lot or consignment of bullion presented for purchase at the Mint. Clearly this would require identification and segregation of silver by custom smelters and refineries that would be entirely impracticable in view of the customary practice of combining various lots of ore, concentrate, or base bullion for treatment. In respect of ores already in process this would be physically impossible. The smelters therefore were only protecting themselves when they settled at the market, or New York, price rather than at \$1, until such time as an understanding could be reached with the Federal officials. They have proposed that the Government agree to purchase at the fixed price a quantity of silver equivalent to the amount that can be proved to have been recovered from ores mined and treated exclusively in this country, without demanding the identification of the actual metal as having originated within our boundaries. The remainder, coming from Canada, Mexico, or elsewhere, the smelters or refiners, of course, will have to sell in the open market. On the recommendation of Mr. Raymond T. Baker, Director of the Mint, the Treasury department has, we believe quite properly, acquiesced in this arrangement, and the legal authorities have advised that it is in accord with the law, so that hereafter any company mining silver in the United States is entitled to a settlement on a basis of the fixed price, \$1 per ounce, from the smelter to whom it consigns its ore, subject, of course, to the usual terms of its contract, and providing the affidavit as to origin is made. Certain changes in the form and sequence of the affidavits are under consideration. These, however, are simply for greater convenience and simplicity; they will have no essential effect on the settlement. It is important to note that the position of those mining companies whose immediate output is sold to the Government in the form of bullion is not in any way affected, so long as no part of the content of such bullion comes from outside the United States. As we have pointed out before, the only requirement is that the combined gold and silver content of their product amounts to 200 parts in 1000. The Mint does not purchase bullion containing more than 800 parts of base metal, but the proportion of gold as compared with silver is immaterial. The Director, however, may specify delivery at New York, Philadelphia, Denver, or San Francisco, at his option. The domestic output of silver last year was 55 million ounces, so that at the present rate of production four years will be required to supply the 207 million ounces that already has been ordered to be purchased by the Director of the Mint. Should the market price reach \$1, purchases under the Pittman Act would cease automatically for the time being, so that

there is a probability of this four-year period being increased measurably. It will be recalled that under the authority of the Act the Treasury actually melted and sold 271 million dollars to supply the foreign demand, principally from India and China. This need has now apparently been satisfied; at the same time the melting of silver coins in France, Germany, and other countries in continental Europe and the recent monthly production of about \$6,000,000 in Mexico have been factors operating toward the collapse of the price in the open market. The Government is not suffering any loss in making purchases at a price above the market, because an equivalent amount was melted and sold at \$1 per ounce plus all costs incident to the transaction.

Mr. Sulman and Minerals Separation

The May issue of 'The Mining Magazine', of London, contains an editorial entitled 'The Attack on Mr. H. L. Sulman', and on another page there appears a letter from Mr. Sulman himself. The front page of the same issue of 'The Mining Magazine' is devoted to an advertisement of the Minerals Separation company, but the coincidence should suggest a lack of the sense of humor rather than a sinister inference. The editorial is an echo of Mr. Sulman's letter and calls for no comment, except its lame attempt to establish an analogy between Dr. F. G. Cottrell's gift of his fume patent to the United States government and Mr. Sulman's sale of his flotation patents to the Minerals Separation company. The mere statement suffices to expose the absurdity of the comparison. Mr. Sulman's letter calls for a reply, as it is directed in large part against the criticisms appearing in these columns. Before starting to answer him, we record the fact that on May 25 Mr. Ballot filed a copy of Mr. Sulman's letter, as published in 'The Mining Magazine', with the U. S. Circuit Court of Appeals for the Third District, before which the case of Miami Copper Co. v. Minerals Separation Ltd. is now being re-heard. To come to Mr. Sulman: he says that attacks have been made upon him by "a small section of the American technical press". He is mistaken; the criticism has come from all the technical papers interested in metallurgical matters. He charges our technical press with an improper motive, namely, the creation of a hostile opinion designed to prejudice the trial of the suits brought by Minerals Separation in the United States. This is hum-combe. Speaking for ourselves, we have ventilated the subject, not of Mr. Sulman alone but of the doings of his company in the United States, because it was one of immediate interest to our readers, that is, to those engaged in mining and milling. We have a strong conviction that froth-flotation was not discovered by Mr. Sulman or by the Minerals Separation people, but by technicians in the Central mill at Broken Hill in 1904, namely, Messrs. F. A. Beauchamp and Wilton Shellshear, under the direction of Mr. James Hebbard, the manager of the Central mine. We base this conviction on statements made to us personally by Messrs. Beauchamp and Shellshear, and by

the published statement of Mr. Hebbard in the Proceedings of the Australasian Institute of Mining Engineers. In December, 1904, says Mr. Hebbard, tests in the Central mill, using only 0.75%, that is, less than 1%, of oil, gave results that were "excellent, with all float-concentrate, no granular material being formed". The "granular" refers to the fact that the discovery of the efficiency of a minute proportion of oil came gradually, in the course of experiments started in 1901, in which the Cattermole sinking process was superseded finally by the flotation method. We have quoted this statement of Mr. Hebbard's repeatedly, because it proves to us, and to any detached onlooker, that the 'discovery' claimed to have been made by Messrs. Sulman, Picard, and Ballot in March, 1905, is fictitious. Apart from the correspondence between Broken Hill and London, it may be recorded that Mr. G. A. Chapman went from the Central mill to the Minerals Separation office in London in the last days of 1904.

We have opposed the exactions of Minerals Separation because we believe that the company is not entitled to a monopoly of the process and also because their methods have been extortionate, unfair, and prejudicial to metallurgical progress. They tried unsuccessfully to prevent us from publishing technical information on the flotation process, as already recorded in these columns. Our answer was the publication of two books on the subject within the following three years. Mr. Sulman tries to distinguish between the American company and the parent company. He says that his holding in the American company is only a tenth of 1%, but even that is a 'critical' proportion, having regard to the amount of tribute collected and to be collected. Moreover, the evidence given recently before the Federal Trade Commission shows that the parent company holds all but 7% of the shares in the American company. Whatever Mr. Sulman's shareholding may be, as the principal patentee and as metallurgist to Minerals Separation, he is identified with that company, to whose affairs he has devoted his energies since the company was first organized. As to the "pothier" about his paper, he asks the cause of it. We answer. The reason why his paper has drawn so much attention is, in the first place, that it was given as the reason for awarding him the gold medal of the Institution of Mining and Metallurgy. This was done at a time when the American mining industry was resenting bitterly the demands and impositions of a patent-exploiting agency with which his name is identified. Mr. Sulman, of course, is not known in this country outside his connection with the Minerals Separation company. In his paper he drew attention to that connection by going out of his way to compliment the chairman of the company, Mr. John Ballot, who is more particularly identified with the unpleasant business methods of Minerals Separation. The award of the medal to Mr. Sulman was a slap in the face of the American mining public. The gentlemen who made the award did not realize this fact, because, as yet, Minerals Separation has not made itself so thoroughly disliked by British mining companies as it has by the American. Flotation as a process is not nearly

as important to the British mining engineer as to the American; the one important mining centre where froth-agitation is used on a large scale is Broken Hill, and there it has to compete with two or three other flotation processes, so that relief is available. It all depends whose ox is being gored. Mr. Sulman objects to the adjective 'belated' as applied to his paper, which was read before the Institution and served as the pleasant excuse for awarding the gold medal to him. He suggests that we called it "slovenly in presentment", when, on the contrary, we went out of our way to compliment him on the clarity and evident care with which it was written. But it was not only "belated", it was resurrected. The original treatise was written in 1906, thirteen years before he read his recent brochure. A copy of the "typed booklet", as he calls his original and elaborate treatise of 1906, is now in the hands of the Circuit Court of Appeals at Philadelphia, where it serves as evidence to show that the Minerals Separation company has construed its basic patent in a manner not in accord with the interpretation of the patentees, Messrs. Sulman and Picard, as recorded by them in 1906, three years before patent No. 835,120 was assigned to Minerals Separation. The "atmosphere of mystery and suspicion", as Mr. Sulman describes it, was created neither by Sir Thomas Rose's remark nor by Mr. T. J. Hoover's reference, but by our knowledge of the fact that Mr. Sulman did write a comprehensive treatise in 1906, that a copy of it was in California, and that his recent be-medalled paper was largely a rehash of it, with such excisions and alterations as would adapt it to the exigencies of pending litigation. On another page we publish the affidavit of Mr. Theodore J. Hoover as filed at Philadelphia. Mr. Sulman asks: "I would inquire by what law, ethical, legal, or sentimental, I am required to keep the world informed in print of the progress of my views". This is a nice piece of rhetorical confectionery, but it is beside the mark. Our point is that the Institution has set the stamp of its approval upon secrecy in the arts, it has honored a metallurgist who kept back valuable information for 13 years, and who was associated with men that made it their business to stifle the publication of technical information essential to progress in the art of metallurgy. When, at last, he publishes his moth-eaten views on the subject, he is applauded and rewarded by the greatest distinction within the gift of the Institution, and the secretary of the Institution emphasizes the fact by specifically informing the press that the award is the very highest in its gift. Some of our friends in London have written to say that they thought us ungenerous in our criticisms of Mr. Sulman. We have no grudge against Mr. Sulman, but we hate humbug and we resent the apparent endorsement of Minerals Separation, through Mr. Sulman, all the more as he, in his paper, went out of his way, not to dissociate himself from Mr. Ballot's policy, but to tender him a highly perfumed bouquet. If the medal had been given to Mr. Sulman at any other time or for any other reason, it would not have concerned us; but given at this time and for such reasons as those stated, we protest unhesitatingly.

DISCUSSION

Some Observations on Smelting

The Editor:

Sir—Being confronted with a problem in the disposal of copper concentrates and ores, and smelting having been sadly neglected during my technical education and training, it became urgently necessary for me to make good the delinquency. Therefore, I collected all the available reading-matter on the subject, such as books, bulletins, pamphlets, papers, and articles, and being a lone white man in a remote corner of the world, I had ample time during the long winter evenings to peruse and thoroughly digest them.

I found the reading-matter most entertaining and must congratulate the smelting-men on having compiled a mass of such interesting and, at the same time, informative literature. But, while reading, I noted an idea that prevailed so persistently as to almost amount to an obsession; the idea being the paramount importance of concentration, and the contempt of the experts for any process that yielded low concentration was indeed ill concealed. For example, E. D. Peters in his classic treatise on the 'Practice of Copper Smelting' passes lightly over the highly interesting pyritic process at Tilt Cove, Newfoundland, as being hardly worthy of attention from real smelting-men, because the concentration was only two into one, and the same attitude is apparent throughout.

Consequently, during my course of study, the question continually occurred to me, "Has not froth-flotation entirely revolutionized the art of smelting?" or, in other words, "Does it really pay to eliminate worthless earthy gangue-material from copper ores by a complicated process working at 1300°C. when the same thing can be done better by a simple process working at 13°C.?" I use "really" and "earthy" advisedly. If this question can be answered in the negative, then the Tilt Cove process with its 2:1 concentration, its simplicity, and its entire lack of costly extraneous fuel, becomes the process, and all others (with some exceptions) become back numbers. The exceptions are those plants treating ores in which the gangue is predominantly sulphide of iron; because froth-flotation is not a pronounced success when it comes to separating one sulphide from another, and even if it could not compete with a process that on a diet of mere wind, flavored with a little coke, treats lump ore direct from the mine.

Of course the smelter-men will exclaim, "Yes, but your ideas are all awry, because our present methods will not permit flotation concentrate to be smelted according to Tilt Cove practice"; and from what I have read I

must admit that this appears to be so. But is it absolutely impossible to change the methods?

With clean silicious copper sulphide ores, a froth-flotation plant should recover 95% of the copper, in a concentrate assaying from 20 to 25% copper. Such a concentrate by simple melting will produce a matte going 25 to 30% copper, and by afore-mentioned books and bulletins tell me that such a matte is suitable for converting in the modern basic-lined converter. Therefore it appears likely that smelting will drop its 's' and become plain melting, that is, melting flotation concentrate so that it can be poured into a converter and blown to 'blister'. Of course, the flotation concentrate will contain some earthy substances, which will have to be removed during the melting operation, but I shall come to these later.

Coming now to the matter of generating heat for the melting operation. In my smelting literature, especially the more recent publications, I see many references to pulverized coal for conventional reverberatories and also blast-furnaces. On reading of this pulverized fuel, the thought crossed my mind, "Why, what about flotation concentrates as a pulverized fuel?" As proceeded, it is approximately the same degree of fineness as pulverized coal—80 to 90% through 200-mesh, and a large proportion practically impalpable powder (probably several thousand mesh)—so that its physical properties are all in order. Now what about its thermo-chemical properties? The following problem will elucidate the point: A flotation concentrate containing 20% copper as chalcopyrite and 15% quartz gangue (for simplicity), the rest being pyrite, is to be burned as a pulverized fuel. The 'ash' is to be a 50% copper matte and a corresponding ferrous silicate slag. What is the calorific value of the fuel? With the help of our faithful friend and guide, Richards' 'Metallurgical calculations', I solved this problem and obtained as result:

Calorific value = 1250 B.t.u. per pound.

The equation shows that 16 cu. ft. of air is required per pound of fuel, hence the calorific value of the fuel-air mixture is 80 B.t.u. per cubic foot—easily comparable with the calorific value of the gas-air mixture used for firing open-hearth steel-furnaces. I am fully aware that there are some vital differences in the processes of combustion of these two fuels, but this is a matter of mechanical arrangement and detail. The same calculation brings out some interesting points: it shows that the ash constitutes 82% by weight of the fuel burned—a vital point of difference between this fuel and ordinary pulverized fuels, where the ash usually amounts to less than

20%. Fully 40% of the fuel goes into the ash as matte, and 42% as slag. The slag lies between a 'unit' and a 'sesqui' silicate, therefore it should be quite satisfactory, and as the weight of the slag and of matte is approximately equal, the slag can run much higher in copper than usual without causing losses of any moment. Further calculations show that the theoretical temperature attainable, using cold air and cold fuel, is 1436°C.; while, if the air be pre-heated to 300°C. and the fuel to 200°C., the theoretical temperature becomes 1618°C.; and as there is practically no limit to the rate at which the furnace could be driven, the actual temperature should approach very near to these theoretical temperatures. Taking actual data from an operating blast-furnace plant, Richards shows that the theoretical temperature is 1569°C., so it is safe to assume that this hypothetical furnace burning concentrate as pulverized fuel could be maintained at a temperature sufficiently high to conduct the smelting operation without extraneous fuel, and at the same time have sufficient heat to spare to melt a little miscellaneous lump material that might happen to be about the premises. However, to tide the process over the rough spots, the judicious use of a little electric current might be advisable, especially in districts where water-power is available. As the annual production of electric steel will approach the 1,000,000-ton mark when the world settles down to work again, the application of electric energy to metallurgical furnaces can be said to be well past the experimental stage, so there is nothing particularly outrageous in the above suggestion.

This is not 'pyritic' smelting; it is much better than that. My books and bulletins tell me that in the pyritic process somewhat less than half the sulphur is available for fuel and matte-formation, the rest actually extracting heat from the furnace by being volatilized. While in the above suggested smelting scheme, the whole of the sulphur (other than that required for the matte) instantaneously flashes into SO_2 , in the same manner that the carbon of the pulverized coal flashes into CO_2 . Incidentally, one of the most interesting possibilities is the enormous capacity per unit-volume such a furnace would have. This is where the new pulverized fuel will differ most from the old. The present metallurgist prides himself on the smallness of the weight of fuel he can burn in a given volume (*vide* the large coal-dust fired reverberatories), but the future metallurgist will take special pride in the smallness of the volume in which he can burn a given weight of fuel.

So here in flotation concentrates we have a valuable pulverized fuel, which is being produced in enormous quantities, and which the mines would be pleased to deliver to the smelters gratis, free, and for nothing. In this connection, during my course of reading, I frequently came across something that seemed to me to be extraordinary. It appears that at many plants today wealth is being dissipated by destroying a perfectly good pulverized fuel by a process of slow combustion (roasting), then further wealth is being dissipated by burning another valuable pulverized fuel (coal) in the propor-

tion of 1:6, in order to melt the 'ashes' from the first perfectly good pulverized fuel. This would appear to be nothing less than rank bolshevism, and as such I commend it to the serious attention of the officials of the U. S. Department of Justice now on the trail of the Reds.

After making some further calculations to make sure that my theory was all in order, I started to make an experiment. My equipment consisted of a miscellaneous assortment of crucibles, piping, tubing, valves, ejectors, montejus, combustion-tubes, a wind-furnace, and compressed air. My material was an ordinary flotation concentrate containing 22% copper and 18% earthy gangue.

After burning numerous holes in a perfectly good suit of clothes, and making a genuine Stetson look as if it were in the throes of an attack of black small-pox, I succeeded in burning my pulverized fuel so as to yield an intense heat and leave an ash consisting of a 47% copper matte, and a satisfactory slag. The process was not self-sustaining thermally, but this was only to be expected considering the voracious appetite of small furnaces for heat. The dust and fume losses did not appear to be excessive; but, in any case, dust and fume have lost most of their terrors since the perfecting of the Cottrell process.

In view of these results and my unbounded faith in the ability of the men who were responsible for the literature I have been reading, with a reasonable amount of luck, I expect to live to see the day when we are going to be introduced to something new, something revolutionary, something fit to take its place beside cyanidation and froth-flotation. The pyritic process was a step in the right direction, but unfortunately, as developed, it is of limited application. The smelting problem is not solved until every mine, irrespective of locality, can have its own smelter and turn out its own blister copper. All the ingenious amalgamating devices did not solve the problem of precious-metal recovery; all the wonderful refinements in gravity concentration did not solve the base-metal concentration problem; likewise all the improvements in standard conventional practice are not going to solve the smelting problem. To reinstate the reverberatory is simply to revert to the cruder methods of a century ago.

H. H. S.

Kokai, Chosen, May 6.

ONTARIO'S production of crude petroleum was reported by J. C. Waddell, supervisor of bounties, to be 220,100 bbl. in 1919, a decline of about 68,000 bbl. from the 1918 output, due chiefly to the failing production from the Mosa Township field. The Petrolia field, now entering the fifty-eighth year of production, shows an increased output of about 4600 bbl. The Tilbury field has been divided into Tilbury East and Dover West, the latter producing 16,705 bbl. from the Trenton formation. The Union Natural Gas Co. has seven producing wells in this field, and the Petrol Oil Co. completed one in October and is now drilling another.

The Measurement of Ventilating Air

By WALTER S. WEEKS

INTRODUCTION. The quantity of ventilating air in circulation is estimated by obtaining the velocity of the air at a section of a mine-opening whose area is known, and multiplying this velocity by the area. The velocity in feet per minute multiplied by the area in square feet gives the cubic feet per minute.

The instruments in general use for determining the velocity are the anemometer and the Pitot tube.

THE ANEMOMETER is a small windmill geared to a pointer which revolves on a dial. The dial is arranged like that of a gas-meter with small dials where the hundreds, thousands, and tens of thousands are recorded. Between the wheel and the recording apparatus is a tiny clutch, or disconnector, so that the recording mechanism can be thrown in or out at will. The instrument records the linear feet of air that pass through the vanes; for

for one minute with the clutch thrown in. It is necessary to take the velocity at a number of different points in a section of a drift because the velocity varies. It is least near the walls and greatest near the middle. If the operator holds the anemometer in his hand, his body in

FIG. 1. STANDARD TYPE OF ANEMOMETER

FIG. 2. ANEMOMETER MOUNTED ON A STICK

FIG. 3. HIGH-SPEED ANEMOMETER

instance, if the instrument is held in the air current for three minutes and it reads 900, the velocity is 300 ft. per minute. The favorite size of anemometer for mine use is 4 inches in diameter. They can be obtained with a mechanism by means of which all the dials can be set back to zero. This is not necessary; but it is convenient. Fig. 1 shows an anemometer of the type generally used.

To obtain the velocity of the air in a drift a point should be selected where the drift is uniform for some distance. The area at this point should be divided into sections by strings or by eye and the velocity should be obtained in each by holding the anemometer in the centre

the airway may be a sufficient obstruction to cause error in the determination.

A more accurate determination may be obtained with an anemometer mounted on a stick. Fig. 2 is an instrument of different design so arranged. The clutch is thrown in by a thread and thrown out by an elastic band. With this arrangement the operator may stand entirely out of the current when taking a reading.

The ordinary anemometer can be used for air velocities up to 2000 ft. per minute. The wheel begins to turn when the velocity is from 30 to 50 ft. For velocities below 50 ft. a special instrument must be used. For high

velocities such as are met in ventilating-pipes, an anemometer of more rugged construction is necessary. Fig. 3 is a photograph of a high-velocity anemometer which can be used up to 6000 ft. per minute.

CALIBRATION. For measuring velocities from 50 to 1200 ft. per minute the anemometer is the best instrument available, but it is usually inaccurate. It is commonly calibrated in this way: A long arm is arranged to be revolved in a horizontal plane about one end as a centre. The anemometer is mounted on the outer end with the axis of the wheel horizontal and at right angles to the arm. If the rate of rotation is known the velocity of the anemometer through the air can be calculated and the instrument thus calibrated. This method causes air currents that are not exactly comparable with straight-line flow. Again, the heavier the air the faster the wheel will turn in a current of given velocity, so the anemometer at high altitudes is liable to give low results. The slightest change in the angle of the blades will change the action. They are easily bent.

As an instrument for obtaining the absolute velocity of the air, the anemometer is poor, but as an instrument for obtaining the relative amounts of air in the mine-openings, the anemometer serves a most useful purpose.

THE PITOT TUBE. For testing ventilating-fans it is necessary to know the absolute velocity of the air. For this work a Pitot tube is used. The theory of it should be understood.

Suppose we have a small pressure-fan blowing into a pipe. We wish to measure the static pressure in the pipe where it joins the fan. It has been proved by experiment that when air is flowing with uniform velocity in the pipe, the static pressure is the same all over the pipe. In order to obtain static pressure accurately there must be no impact of the air against the opening where the measurement is taken. A pin-hole is all that is necessary to transmit static pressure, so if we take a small metal tube with one end sealed and bore a pin-hole in the side of the tube, this hole, if placed toward the side of the ventilating-pipe will transmit the static pressure accurately to the inside of the tube when the open end of the tube is connected with a water-gauge, or manometer, as it is called. The difference in level of the water in the two legs of the manometer will indicate the static pressure.

If we point the end of a small tube against the air current and connect the other end to a manometer, the manometer will record the sum of two pressures. First it will record the static pressure existing in the pipe, and secondly it will record the pressure due to the impact of the air striking against the end of the tube. If we connect the pin-hole tube to the other end of this same manometer we subtract the static pressure from the sum of the static and impact pressures and so the manometer will read only impact pressure. If we can determine the relation that exists between the impact pressure and the velocity of the air, we have a simple means of measuring velocity.

The apparatus just described is in essence the Pitot tube. In the modern Pitot, however, the static and im-

pact tubes are combined into one instrument. Fig. 4 is a section of a tube from the code of the American Society of Mechanical Engineers. *A* is the end that faces the air current and is acted upon by the static pressure and by the impact of the air. The pressure at *A* is the pressure in *G*, which is connected to one leg of the manometer. The tube *G* passes inside the tube *H*, but is connected with it in no way. *C*, *D*, *E*, and *F* are pin-holes. The pressure in *H* when connected to the manometer is the static pressure of the pipe. When *G* and *H* are connected with the two legs, the manometer records the impact pressure. We must next study the relation that exists between the impact pressure and the air velocity.

The usual explanation of the operation of the Pitot tube involves the energy equation

$$v = \sqrt{2gh}$$

and a head of water in the manometer is supposed to be held up which is equivalent to a head of gas equal to $\frac{v^2}{2g}$ which is the velocity-head of the flowing gas.

This explanation is incorrect. The problem is not one of energy, but of impact. The gases are deflected by the point of the tube and an impact pressure is produced. In Fig. 5 a stream of air is flowing along a smooth surface and is deflected by a vane *BD* through the angle *z*. What pressure does the stream exert at *B* in the direction *ABC*? In other words, what force is trying to move the vane *BD* in the direction *BC*?

The stream is flowing with a velocity of *v* feet per second along *AB*. After deflection the velocity along *BD* is, of course, the same, but the velocity in the direction *ABC* is *v* cos *z*. Let us consider a small particle of air of weight *dw*. This has its velocity changed from *v* to *v* cos *z* in the time *dt*. The deceleration in the direction *ABC* is $\frac{v - v \cos z}{dt}$

The force to change the velocity is $F = \frac{dw}{g} \left(\frac{v - v \cos z}{dt} \right)$
 $\frac{dw}{dt}$ = weight flowing per sec., or *W*; so $F = \frac{Wr}{g} (1 - \cos z)$

Let *w* = weight of 1 cu. ft. of air.

Let *a* = area of the stream.

$$W = w a v$$

$$F = \frac{w a v^2}{g} (1 - \cos z)$$

$$\frac{F}{a} = \frac{w v^2}{g} (1 - \cos z)$$

$\frac{F}{a}$ is the pressure in pounds per square foot exerted on a section at right angles to the stream.

The end of the Pitot tube deflects the air current in the same way and the pressure is produced in the same way, but the shape of the stream lines are such that different parts of the stream are deflected at different angles. The cumulative pressure, however, is such that the unit pressure on the end of the tube is $\frac{1}{2} \frac{w v^2}{g}$ with the type of tube now in use. This has been proved experimentally by calibrating the tube with a very accurate meter.* Thus,

*W. C. Rowse, 'Pitot Tubes for Gas Measurements', Journal Am. Soc. M. E., September 1913.

while the impact pressure has the same value as the velocity pressure, there is no causal connection between the two.

MEASUREMENT OF PRESSURE. This impact pressure is measured with the water manometer when the tube is connected in the manner already described. We must now determine the relation between the velocity and this

FIG. 4. SECTION OF PITOT TUBE

head of water. 60 F. will be taken as the standard temperature of water. The weight of one cubic foot of water at this temperature is 62.37 pounds.

$$\frac{w}{2g} v^2 = \frac{i}{12} \times 62.37 \quad i = \text{head of water in inches.}$$

$$g = 32.174$$

$$v^2 = \frac{2i \times 32.174 \times 62.37}{w \times 12}$$

$$v = 18.29 \sqrt{\frac{i}{w}}$$

Velocity in feet per minute or

$$V = 60 \times 18.29 \sqrt{\frac{i}{w}} = 1097.4 \sqrt{\frac{i}{w}}$$

i is the reading of the manometer in inches and w is the weight of air in pounds per cubic foot.

THE WEIGHT OF AIR. The weight of a cubic foot of air depends upon its pressure, temperature, and mois-

FIG. 5. SHOWING DEFLECTED STREAM

ture content; so, to determine its weight, we must have a barometer and a sling psychrometer.

A sling psychrometer is a combination of a wet-bulb and a dry-bulb thermometer that can be whirled around. Fig. 6 shows a handy type. It is whirled around by the chain. With the kind permission of the Buffalo Forge Company I am able to use the tables for determining the weight of a cubic foot of air. This table (No. 1) is from their handbook, 'Fan Engineering'. (See following page.)

An example will illustrate its use: The barometer is 29.3 in., the dry-bulb temperature is 62°F., the wet bulb

FIG. 6. SLING PSYCHROMETER

is at 40° F. What is the weight of one cubic foot of air under these conditions?

The weight of one cubic foot of saturated air at 29 in. and 60° F. is 0.07353. Call this *a*.

Decrease in weight per degree increase in dry bulb is 0.00016. Decrease for 2° is 0.00032. Call this *b*.

Increase in weight per 0.1 inch increase in barometer

FIG. 7. PIPE TRAVERSE

is 0.00026. Increase for 0.3 in. is 0.00078. Call this *c*.

Increase in weight per degree difference between wet and dry bulb readings (see last column) is 0.000026. For 22° it is 0.000572. Call this *d*.

Weight of one cubic foot of air = $a + c + d - b = 0.07456$ lb.

To determine the pressure inside a pipe, the difference in pressure between the inside and outside of the pipe as shown by a water-gauge must be added to the barometric pressure outside.

DETERMINATION OF AVERAGE VELOCITY. If the air-duct is rectangular it must be divided into small rectangles, twelve or more, and the velocity determined in the centre of each rectangle. If the duct is circular, it is usually divided into three or more equal annular areas and four readings are taken on the central lines of each area. In Fig. 7 the heavy lines mark the boundaries of three equal areas and the dotted lines are the central lines of these areas. Two axes at right angles are assumed to cross the section and readings are taken where these axes cross the dotted lines.

A traverse of the pipe is made first along the axis *AB* by inserting the tube at *A* and taking readings at 1, 2, 3, 4, 5, 6. It is then inserted at *C* and readings taken at 7, 8, 9, 10, 11, 12. The velocities are calculated for each point and the average of these velocities gives the average velocity of the air in the pipe. To simplify the placing of the tube we should know the distance from the outside of the pipe to the points where the readings are taken. These distances may be obtained from Table No. 2, which gives distances from the edge of the pipe to the point on the traverse in percentage of pipe-diameter when three equal areas are used.

Table No. 2

Point	% of <i>D</i>	Point	% of <i>D</i>
1	4.5	4	70.4
2	14.7	5	85.3
3	29.6	6	95.5

For example, suppose the pipe 10 in. diam., the Pitot tube would be inserted through a hole in the side and

readings taken at the following distances from the edge of the pipe: 0.45 in., 1.47 in., 2.96 in., 7.04 in., 8.53 in., and 9.55 inches.

LABOR SAVING DEVICE. To obtain the average velocity, it is incorrect to average the manometer readings, be-

FIG. 9. DETAILS OF PITOT TUBE

cause the velocity is a function not of i , but of the square root of i .

$$V = 1097.4 \sqrt{i_w}$$

To obviate the labor of calculating the velocity each time, we may plot a chart with values of i as abscissae and $1097.4 \sqrt{i}$ as ordinates.

$$\text{Let } A = 1097.4 \sqrt{i}$$

We take our 12 readings in the pipe and for each manometer reading take the corresponding A from the chart. These values of A may be averaged. This average multiplied by $\sqrt{\frac{1}{w}}$ gives the average velocity.

Table No. 3 gives the values of A for different values of i . This is given in order that a large chart may be plotted.

0.95	1069.6
1.0	1097.4

Every once in a while somebody pops up with the idea of saving labor in obtaining the average velocity by placing a lot of Pitot tubes in the pipe and connecting them with one manometer. The impact pressure varies with the square of the velocity, so the result will be that air will flow in through the tube where the pressure is highest, pass through the manometer and out through the other tubes. Such an arrangement might by chance give the correct result, but so might a ouija board.

CONSTRUCTION OF THE PITOT TUBE. Let us now consider the instruments with which we work. Fig. 8 is a photograph of a Pitot tube. The outside or static tube is made of seamless brass tubing 0.146 in. inside diameter. The inside tube is made of seamless brass tubing 0.046 in. inside diameter. The construction of the tube is shown

FIG. 11. INCLINED MANOMETER

in Fig. 9, *a* and *b*. The horizontal part *D*, Fig. 8, is about four inches long. Two holes are bored on the side of the outside tube two inches from the tip. The holes are 0.02 in. diam. The rod *C* is for alignment. *A* connects with the inside tube, *B* with the outside.

Fig. 12 shows the manner in which the Pitot tube is mounted for traversing the pipe. Nails are driven in the frame for the support of the tube at such points as will place the tip of the tube at the correct position in the pipe.

FIG. 12. A PITOT TUBE IN OPERATION

THE MANOMETER. In Pitot-tube measurements we deal with very small pressures, so a very sensitive manometer is necessary. We can obtain any magnification desired by inclining the ordinary U-tubes. Fig. 10 is the American Blower Co.'s inclined manometer. This can be set for any magnification. Fig. 11 is a manometer that I had constructed for laboratory work. It is too cumbersome for the field. The air-tight tank *A* is one leg of the manometer and the glass tube *B* is the other leg. They are connected by the rubber tube *E*. The tank is so much larger than the area of the tube that the pressure is obtained by reading the rise in the glass *B* alone. The glass tube may be set at any angle by means of the slow-motion screw *F* and the clinometer *G*. The static plus velocity tube is connected at *C* and the static tube at *D*.

The glass tube is first set at the desired angle. The tank *A* is then adjusted until the

level of the liquid is at the lower end of the inclined glass tube. The zero of the sliding scale *H* is then set at the line of the liquid.

Although our calculations for velocity involve the weight of water at 60°F., water is not used in the sensitive manometers because it sticks to glass. Gasoline or alcohol of known specific gravity is used and the corresponding head of water calculated. I have been able to obviate this calculation by the use of the clinometer *G*. Suppose we are using alcohol and we wish a magnification of 5:1. We first get the specific gravity of the alcohol with a hydrometer standardized for water at 60°F. Assume that the specific gravity is 0.8. Now if we had water in the manometer, for a magnification of 5:1, the water would have to rise 5 inches along the incline to reach a vertical height of 1 inch or the inclination of the tube would be the angle whose sine is $\frac{1}{5}$. But we have a liquid that requires 1.25 in. vertical height to be equivalent to 1 inch of water. So if we wish to read directly in inches of water, of course, with the magnification, we must set the tube at the angle whose sine is $\frac{1.25}{5}$. The

magnification factor may be eliminated by re-numbering the scale and then we have an instrument in which we use alcohol instead of water and which magnifies the reading as desired and yet reads directly in inches of water at 60°F., which is the weight used in calculating the formula. The clinometers are stock instruments. They should have a vernier reading to five minutes at least. The value of one division of the level bubble is usually one minute, so if we set the vernier to the nearest five minutes, we can get two minutes with the level bubble and thus set the manometer to the nearest minute. The clinometer and re-numbered scale can be applied to the ordinary inclined U-tube. The position of the liquid can be read to a hundredth of an inch.

To be sure there is no misunderstanding of the use of the formula let us work one example. The manometer reads 0.2 in. The weight of one cubic foot of the air is 0.081. What is the velocity?

$$V = 1097.4 \sqrt{\frac{f}{w}} = 1097.4 \sqrt{\frac{0.2}{0.081}}$$

$$V = 1724 \text{ ft. per minute.}$$

[This is the third of a series of articles by Professor Weeks on the ventilation of mines. The first article, 'The Friction of Ventilating Currents', appeared in the issue of April 24, and the second, 'The Theory of the Centrifugal Fan', was in the issue of June 12.—EDITOR.]

Proposed Code of Ethics

A special committee of the American Society of Mechanical Engineers has submitted a 'Code of Ethics' for consideration by the Society. It is recommended that steps be taken to make the new code a joint effort of all the professional engineering and architectural societies; and that Engineering Council or a similar joint professional body be requested to appoint a committee from all the technical societies to prepare a new common Code

of Ethics, which can then be approved and adopted by individual organizations if they see fit. Suggestions are made as to the method of administering and interpreting the code, the articles of which, as recommended, are:

1. The mechanical engineer should be guided in all his relations by the highest principles of honor, of fidelity to his client, and of loyalty to his country.

2. His first duty is to serve the public with his specialized skill. In promoting the welfare of society as a whole he advances his own best interests, as well as those of the whole engineering profession.

3. He should consider the protection of his client's or employer's interests in professional matters his essential obligation, provided these interests do not conflict with the public welfare.

4. He shall refrain from associating himself, or continuing to be associated, with any enterprise of questionable or illegitimate character.

5. He can honorably accept compensation, financial or otherwise, from only one interested party unless all parties have agreed to his recompense from other interested parties.

6. He must inform his clients of any business connections, interests, or circumstances, such as might influence his judgment or the quality of his service to his clients.

7. He must not receive, directly or indirectly, any royalty, gratuity, or commission on any patented article or process used in the work upon which he is retained without the consent of his clients or employers.

8. He should satisfy himself before taking over the work of another consulting engineer that good and sufficient reasons exist for making the change.

9. He must base all reports and expert testimony on facts or upon theories founded only on sound engineering principles and experience.

10. He must not regard as his own any information which is not common knowledge or public property, but which he obtained confidentially from his client or while engaged as an employee. He is, however, justified in using such data or information in his own private practice as forming part of his professional experience.

11. He should do everything in his power to prevent sensational, exaggerated, or unwarranted statements about engineering work being made through the public press. First descriptions of new inventions, processes, etc., for publication should be furnished only to the engineering societies or to the technical press.

12. He should not advertise in an undignified, sensational, or misleading manner, or offer commissions for professional work, or otherwise improperly solicit it.

13. He should not compete knowingly with a fellow engineer for employment on the basis of professional charges, or attempt to supplant a fellow engineer after definite steps have been taken toward the other's employment.

14. He should assist all his fellow-engineers by exchange of general information and valuable experience or by instruction through the engineering societies, the schools of applied science, and the technical press.

A Study of Electric Detonators

By CARL T. LONG and HUBERT L. PASCOE

INTRODUCTION. This paper is a preliminary report on a study of electric detonators that is being made in the mining department of the University of California, under the direction of Walter S. Weeks, Associate Professor of Mining. Help was also given by G. L. Greves of the department of Electrical Engineering. An investigation of elec-

trolytic alloy of platinum and iridium; it has a resistance of approximately 300 ohms per yard. About an eighth of an inch is used in each detonator. The resistance of the bridge when cold varies from 0.745 to 1.29 ohms. This variation might be due either to difference in length or in diameter. The diameter of the wire is 0.037 mm. and is constant within 0.002 mm.; consequently the variation must result from difference in length. Where soldered to the bare copper wires, forming the terminals, the solder

LEGEND

FIG. 1. CONSTRUCTION OF THE DETONATOR

tric detonators was made with the object of ascertaining the probable cause of misfires, and of determining a satisfactory method for connecting and firing detonators.

GENERAL CONSTRUCTION. The tests were made on instantaneous exploders, the construction of which is shown in Fig. 1. The current enters the exploder through one copper wire, passes through the platinum-iridium bridge of fine wire, imbedded in loose gun cotton, and passes out by the other copper wire. When an electric current, direct or alternating, flows through the connecting wires the bridge is heated to a temperature that depends on the current, the bridge-resistance, the time, and the rate at which the heat generated is radiated and conducted away. Conduction takes place through the copper terminals to which the bridge-wire is soldered, and if the gun-cotton is not in close contact with the wire, radiation takes place through the surrounding air. The heat from the bridge lights the priming charge, which in turn ignites the detonating compound and causes the explosion. We do not know the exact composition of the detonating substance designated in the figure as fulminate of mercury.

THE PLATINUM-IRIDIUM BRIDGE. The bridge-wire is an

FIG. 3. TYPICAL OSCILLOGRAM

FIG. 2. MICROSCOPIC PHOTOGRAPH OF DETONATOR-BRIDGE

tends to run down the wire. This shortens the distance and decreases the resistance of the bridge. For the construction of the bridge see Fig. 2.

EFFECT OF CURRENT ON THE BRIDGE. Various currents were passed through the bridges. They became incandescent when the current was 0.40 amperes and broke at 0.70 amperes. This merely shows that the bridges will carry a current below 0.70 amperes without breaking.

USE OF THE OSCILLOGRAPH. The oscillograph is an instrument used in the observation of electric potentials or currents, as a voltmeter or ammeter, usually when the vibrations are too rapid to be indicated by the customary instruments. It is essentially a galvanometer of short period and can be used to obtain photographic records.

FIG. 4

It was used to determine the time required to fire a detonator and the effect of variations in current on this time; and indirectly to determine the number of units of electrical energy required to fire the different detonators and any relation that might exist between the resistance of the bridge and the time required to fire.

Fig. 3 is a typical oscillogram, showing the record of a detonator exploded under the following conditions: resistance of the bridge, 1,002 ohms; initial current, 0.910 amperes; final current, 0.860 amperes. The first horizontal from the top is a calibration line; the distance between it and the next horizontal, or the line of zero current, represents 0.66 amperes as indicated. Following

along the second line, which is that of zero current, we find that the current amounts to 0.91 ampere when the switch, used to include the detonator in the circuit, is closed. This value is readily determined by reference to the calibration line. For an instant 0.91 ampere is flowing through the detonator, but as the bridge-wire becomes heated, this current decreases on account of the increase in the resistance of the wire. This is indicated on the

FIG. 5

oscillogram by the slope of the current line to the left to the point where the final current is only 0.860 ampere. Then, when the detonator explodes the circuit is broken and the current falls to zero. The third line, which is horizontal for a short distance on the left margin of the photograph, is a record of the voltage impressed. The fourth horizontal line is the zero line of the alternating-current curve shown. The alternating current was used to obtain a time-scale with which to compare the detonator-current curve. For example, the distance marked from crest to crest of the curve corresponds to 0.0173 second. This value corresponds to the frequency of a 58-cycle current. By comparison, the time required to

ture the detonator is found to be 0.025 second.

From the evidence of a great many oscillograms taken the following points seemed to be established:

1. The time required to detonate after the switch was closed varied from 0.04 to 0.0013 second.

2. The speed of detonation increased in proportion to the magnitude of the firing current.

3. The number of units of electrical energy required was found to vary widely, but occasionally results were obtained from one detonator that corresponded with those from others. Although we did not have sufficient information concerning the manufacture of detonators, we believe that this difference may be due to the work of different operators in loading the priming charges in the detonators, and that, if steps were taken to segregate those loaded by a particular operator, misfires from this cause would be decreased. It is apparent that the difference in the time of firing results to some extent from the fact that different amounts of electric energy are required, thus necessitating the flow of current for a longer time for some detonators. It must be remembered that the explosion of one of a number connected in series, as they commonly are, will break the circuit and prevent the remainder from exploding.

4. There is no definite relation between the resistance of the bridge and the time required to fire the detonator.

5. The current decreases as the bridge-wire heats.

Other experiments were performed to determine, if possible, a relation between the resistance of the detonator and the current required to produce explosion. The current was gradually increased until the detonator acted. The amount required varied from 0.35 to 1.00 ampere. The current and voltage at the moment of firing were recorded, but it developed that there was no fixed relation between the resistance of the bridge in an exploder and the current necessary to fire it. Two detonators may be connected in series and with a gradually increasing current one may be fired before the other. The remaining one can then be re-connected and fired on a higher current. A knowledge of the resistance of the bridge does not enable one to predict which exploder will fire first.

THE TEMPERATURE OF FIRING. It was thought that this difference in the amount of current required might hinge on the fact that more heat was required to ignite the priming charge in one detonator than in another. This might be accounted for by differences in the moisture content of the gun cotton employed, in the specific heat of the platinum-iridium alloy, in the length of the bridge (causing different conduction losses to the copper terminals), or in the nature of the contact between the gun cotton and the bridge.

The temperature of the bridge at the moment of firing was then determined, by a method based on the change in resistance of the bridge-wire in ohms per degree of increase in temperature. Then by employing the resistances when the wire was cold and just before detonation, determined by the drop-of-potential method, the change in resistance was calculated. By means of a chart on which

this change from 0° to 1500° had been plotted the temperature of the bridge was determined at the instant of firing. The results indicate that the temperatures vary through a wide range, owing to any one or all of the factors mentioned above.

PRACTICAL CONCLUSIONS. If detonators are connected in series the current may rise to a point that will fire some before the others are affected.

If detonators are connected in series to a high-voltage line, since they require different amounts of electrical energy and shoot at different temperatures, some will detonate and break the circuit before the others reach the temperature necessary for detonation.

The obvious conclusion is that detonators should always be connected in parallel and be subjected to a voltage sufficiently high to ensure a current of at least one ampere through each. The higher the current the better, provided that the line-fuses will not be blown. If the exploders are tested with a galvanometer and shot in parallel from high voltage, misfires will be reduced to a minimum.

In the delay-action exploder another element which may cause misfires is introduced, namely, a short fuse. If the cut-holes of a round, in either shaft or drift, are loaded with instantaneous exploders and the other holes with delay-action exploders, it has been proved that the detonation of the cut-holes may snuff the fuses in the delay-action exploders before they have had time to ignite properly. To obviate this difficulty, it is common practice to use a short delay in the cuts and a longer one in the other holes. This practice may be objected to for two reasons. One of the main arguments for the electric detonator is the fact that the simultaneous explosion of all the cut-holes produces a more effective blast than the same number of successive shots. Delay-action exploders can never be so accurately made that they will all explode at the same time. Even the instantaneous exploders will vary slightly in the time of explosion as we have shown. A more serious point to criticize in the practice of using delays in the cut-holes is the fact that we introduce another chance for misfires. A misfire in the side holes is not so serious, but misfires in the cut-holes cause the loss of the round. We suggest the following procedure.

Three wires are run to the face. The cut-holes contain instantaneous exploders that are connected in parallel to the line-wires as shown in Fig. 4. The side holes contain delay-action exploders connected in parallel to the line as shown. The line-wires are connected to the three-pole switch shown in Fig. 5. It will be noticed that the two left-hand clips (a) are of the same length but longer than the right-hand clip (b). The delay-action circuit is controlled by the left-hand and central clips, while the instantaneous exploders are fired by the central and the right-hand clips. As the switch-handle is pushed down, the delay-action exploders are lighted and get a good start before contact at (b) is made, to fire the cut-holes. The contact should be completed before the first delay fires and this will be accomplished if the switch is closed in the ordinary manner.

The Dorr Bowl-Classifier

By HENRY HANSON

The chemistry of cyaniding was so well worked out by MacArthur, before introducing his process, that no improvement or additions of note have been made since its application to gold and silver ore; but this does not apply to the mechanical side of the process.

When this method of treating precious-metal ores was first introduced and became of commercial importance, the pebble-mill and the ball-mill were given no consideration, and the various types of filters, classifiers, thick-

rakes on the thickener arms, the colloidal material and the fine, largely, going off in the overflow. The oversize and a small amount of undersize pass down through the opening in the bowl to the cleaning or raking chamber. This chamber is relatively small in area as compared to the upper compartment. The thickened pulp, upon entering the lower chamber, is subjected to agitation caused by the reciprocating action of the rakes and the back flow to the upper chamber. This stirring action, aided

THE BOWL-CLASSIFIER IN THE GOLDEN CYCLE MILL

eners, and agitators were unknown. These machines, largely developed in connection with cyanidation, have played an important part, not only in cyanide plants but also in base-metal milling and other industries. The coal industry supplied the metal miner with his best conveying equipment, while the pebble-mill was taken from the cement industry.

The hydraulic cone, the Dorr classifier, and the Dorr thickener all enter into the make-up of the bowl-classifier, the main features of these three being embodied in this single machine. It may be designated as a two-stage inter-return classifier; it consists first of a large settling-chamber in which the first step of the classification takes place; this upper chamber is really a small shallow thickener where the settled material is constantly being raked to the opening in the centre of the thickener by the

by the upward current of the solution, tends to free the colloids and the fine from the coarser material and carry it back into the upper compartment, where it largely passes off in the overflow. Under the most suitable operating condition only a small amount of oversize is held in suspension and passes back into the bowl, where it again settles and is passed down into the raking-chamber. The oversize in the cleaning-chamber is raked forward in the classifier in the usual way. It is possible, of course, to have the agitation in the cleaning-chamber made so violent as to keep a great part of the mass in suspension, in which event great quantities of oversize will be carried back into the upper compartment by the back-flow. The bowl does not break down in its classification even under these conditions, but when operating the classifier with too much agitation in the lower chamber,

there is a tendency for a great amount of material to pass around from one chamber to the other, as if it were in closed circuit. Operating the machine under these conditions naturally reduces proportionately the amount of initial feed that it is possible to handle successfully in the classifier.

Great use is made of the backflow, but this cleansing wash must not be confused with that of hindered settlers, which accounts for the vastly increased capacity of the bowl-classifier as compared to the cone. It would appear, therefore, that, as compared to steep-cone classification, equally good work can be done by the bowl-classifier, this machine requiring less attention in its operation. The capital cost of the bowl-classifier based upon the capacity as compared to cones should also be considerably less. As a separator of colloids, from sand, the work of the bowl-classifier at the Golden Cycle mill, at Colorado Springs, leaves little to be desired.

When a new or improved type of machine replaces another type of equipment successfully, the question naturally asked by the engineer is, what are its possibilities in other fields? It is too early, as yet, to answer such a query, but it would seem safe to predict that the bowl-classifier may become a worthy competitor of the cone and that the drag-belt classifier used in classifying the tailing from the primary or rougher cells into sand and slime, preparatory to table and secondary flotation concentration, may find in the bowl-classifier a machine that will make a closer separation of these products, owing to its greater flexibility, and that will yield itself more readily to the control of the operator.

For the treatment of oxidized copper ores, now found amenable to acid treatment by lixiviation, it is customary to use dry-crushers, the crushing being done by machines that make a minimum of slime, the operation being carried only to such a point as will allow free percolation of the entire product by acid solution. It is, however, likely that the grade and character of some ores of this type is such as to require finer ground material than can be leached without classification and a dual treatment of sand and slime, in which event satisfactory classification would become important.

R. S. Handy, superintendent of the Bunker Hill & Sullivan mill, is quoted* as saying, that if a complete removal of all colloidal material is made, there is little choice as to whether flotation or gravity concentration is used. While this may be true of some ores, it would nevertheless be unwise to apply this statement too broadly without making determinations on the ore in question; but, generally speaking, there is no doubt that a complete removal of colloids, followed by good classification delivering closely-sized products to suitable tables, will add greatly to the effectiveness of the work on the table. Just before flotation came into vogue great refinements were being made in gravity concentration, and no doubt these refinements would have been carried still further had not the successful introduction of flotation greatly simplified the problem of concentrating base-metal ores

when ground to a point where the valuable mineral is released from the gangue.

While the rake and spiral classifiers have played an important part, not only in cyanidation plants but also in flotation, working in close circuit with ball-mills or pebble-mills, there is, however, still room for improvement, as it is at present difficult to obtain an overflow of the necessary fineness from a standard rake-classifier without returning to the mill, with which the classifier is working in close circuit, from 20 to 30% of material already ground sufficiently to require no additional grinding. While it is not likely that a mechanical classifier will be developed that will entirely remove all material of the necessary fineness from the closed circuit, unless it is done by actual screen-sizing on wet pulp, such use of fine grinding has not proved a success owing to the high cost of maintaining the screens and the labor entailed in operating them. In large plants, where very fine grinding is required, the bowl-classifier, with suitable dilution of pulp, should offer, at least, some solution of the difficulty.

The overflow from a classifier, as to sizing, is dependent upon the character of the ore, the fineness of the grinding, the volume overflowing the lip of the classifier and the width of the lip, the amount of mechanical disturbance, and the dilution of the pulp. This last factor is by far the most important, as it is readily seen that the density of the pulp may be such as to prevent any settling or segregation at all. The bowl-classifier therefore has certain advantages over the rake or spiral classifier, such as the much greater overflow-area, that of a 15-ft. bowl-classifier being at the ratio of over 9:1 as compared to the standard rake classifier. The mechanical disturbance caused by the moving rakes is not transmitted to the overflow of the bowl and there is also a more complete removal of the colloids, due to the washing action of the back flow from the lower to the upper compartment.

When at Colorado Springs some time ago I saw a 15-ft. bowl-classifier at work in the Golden Cycle mill. From data given me by A. L. Blomfield, the manager, it would appear that with a feed ranging from 825 to 1650 tons per 24 hours the overflow ranged from 98.41 to 99.44% - 200 mesh, the finer material in the overflow being obtained with the lighter feed. The dilution of the overflow was approximately 10 of solution to 1 of dry slime. From this it is apparent that the machine when operating under this ratio of dilution has its limitation as to the amount of \pm 200-mesh material that can be run off in the overflow. The character of the overflow, however, is controlled by the dilution of the pulp and the volume of the back flow, but just how far these factors can be manipulated to increase the elasticity of the bowl-classifier would naturally become a matter for experimentation. The ore handled at the Golden Cycle mill is roasted, and it is quite likely that the capacity of the classifier would be somewhat affected by attempting to treat a non-roasted ore. This, however, should not be serious, as the overflow-area can be increased readily by enlarging the bowl.

Some Features of the Geological Department of the Anaconda Copper Mining Company

By PAUL BILLINGSLEY

*The Anaconda Copper Mining Co., of Butte, has developed its geological department into an important branch of its organization. This has been the result of a number of factors, but perhaps the chief influences have been the character of the Butte orebodies and the methods of mining required for their development and extraction.

The Butte ores are contained in rather narrow veins in granite (quartz-monozite, to be exact). Widths range commonly from 2 to 20 ft. These veins are cut by at least six successive series of faults, the earlier of which also contain ore-shoots. Thus either in plan or in section the veins are broken and displaced at frequent intervals, the direction and amount of movement varying with each fault, but almost always being enough to throw the ore outside of the drift or raise. When it is considered that the high grade of the ore makes important the recovery of every fragment of vein, and also that many of these faulted fragments are too small to be hit by haphazard cross-cutting, the necessity for an understanding of the structure becomes apparent. From the mine operator's viewpoint it is essential to know promptly which way to turn a working; he is little interested in microscopic details of rock-alteration or theories concerning the source of mineral solutions.

ORGANIZATION. In 1900, an early date as mining geology goes, H. V. Winchell and D. W. Brunton organized a geological department for the Anaconda company, realizing that only the complete compilation of geologic data would solve the problem of fault-structure to the degree necessary for the proper aid to mining operations. The work thus begun has been greatly enlarged in scope and improved in detail under the direction of Reno H. Sales, chief geologist since 1906. F. A. Linforth, who in recent years has been in special control of the work in the Butte mines, has contributed many of the refinements of methods now in use. His paper presented at the Butte meeting of the A. I. M. E. in August 1913, gives an excellent outline of the work as conducted at that time. I follow his article in many points.

REQUIREMENTS OF MINING GEOLOGY. The geological department has thus from its formation kept for its prime objective the helping of the mine foremen and superintendents through a knowledge of the structure of the ground. Its members have realized that the geologist should be the servant of the man who is responsible for the work of the mine. As a result of 20 years of experi-

ment and progress, it has come to regard the following points as essential:

First, friendly co-operation and mutual respect between mine foremen and geologists. The geologist must be familiar with the foreman's plans in order to advise him intelligently, while the foreman must appreciate the value of geologic advice, and be prompt to seek it when in difficulty.

Second, prompt geologic examination of all new workings, in order that suggestions may be made without loss of time. Much useless work is thus prevented.

Third, accuracy in underground observation. Details of structure or of mineralization must be recorded exactly as they appear in the ground—big faults distinguished from minor slips; sequence of veins and faults at intersections properly interpreted; and important minerals, such as secondary chalcocite or primary chalcocite, observed and noted. To take notes properly frequently involves long study under very unfavorable conditions of air, water, ground, etc. Hazy or indefinite notes are only less useless than erroneous ones. If the geologist is not clear in his own mind as to which way the mineralization trends, or as to which of two faults is the intersected, and which the intersector, he should settle the point in the mine, with the evidence before him, and not use indefinite notes as a refuge.

Fourth, immediate platting of notes, and particularly of structural features, upon general geologic maps and sections, in order that the new evidence may be studied in its proper relation to that already accumulated. While I have just pointed out that decisions as to detailed structure must be made underground, it does not follow that general ideas can be correctly gained from that viewpoint. It is one of the most vital features of the work of the department that such general ideas are formulated only upon a study of all available details, each detail as accurate as it can be made by careful work with pick and compass. It is particularly important that one should not let his judgment underground be influenced by what he expects to find. Often a big fault does not come where it is expected; the reason will be discovered in due time.

Fifth, a smoothly-working system whereby conclusions reached by a study of geologic data are translated promptly into terms of mine operations.

METHODS. The means by which these fundamental ends are obtained have been described by Mr. Linforth, but may bear repetition here. Co-operation with foremen is a matter of state-of-mind. The geologist must be humble in spirit. Often the foreman knows more about

*A paper presented at the Western annual meeting of the Canadian Mining Institute in November 1919.

the geology of his mine than he can express in the geological language of professors. Generally he can teach the geologist much about mining methods. Experience would indicate that geologists who have used 'muck-sticks' in their past are apt to have a healthy state of mind in this respect.

Promptness has been secured by enlarging the force of geologists until each man can cover his territory in somewhat less than one month. Many foremen would like more frequent visits. Important faces are visited after each round. It has been found that while a geologist experienced in work at Butte can map correctly 25,000 ft. of workings per month, this gives too little time for the study of special problems in the mines, and does not permit enough trips with the foremen and bosses. At present I should judge that the members of the department cover about 6000 ft. of workings each per month.

Underground notes are taken on loose-leaf sheets on a scale suitable to the amount of detail desired, usually either 20 or 50 ft. to the inch. Colored pencils are used. Red represents vein mineralization, the ore being shown in darker color than the gangue. Blue is used for fault-gouge, light blue for slightly crushed rock, and heavy dark blue for strong clay selvage. With these conventions it is possible to make a drawing that absolutely reproduces the appearance of the face or back of a drift, showing to anyone familiar with the scheme the intensity of mineralization, amount of faulting, direction of drag, etc. The necessity of accurately reproducing the appearance of the ground is greater stimulus to careful observation. In this respect the Anaconda system is superior to others in which mere conventional symbols, such as red dots or crosses, mark the position of ore, or ruled lines of uniform width indicate faults. The fine distinctions which are perceptible underground should appear on the geological maps with equal clarity. Unimportant details such as joint-planes, etc., should be ignored.

In Butte, geological maps are based upon the co-ordinate system used by the mine-engineers. Sufficient sets of convenient size are made to cover the entire district in checker-board manner. The maps are on tracing-cloth, with a separate sheet for each level. In addition to the regular working-set on a scale of 50 ft. per inch, sets on scales of 100 and 200 ft. to the inch are maintained. Mine-foremen are provided with 100-ft. maps covering their own mines, and these are kept up to date by the department. It is of prime importance that the foremen should have for daily use a set of maps on which the geologic structure is shown. The expense entailed by the preparation and maintenance of these foremen's sets is more than repaid by the saving in underground work which results from their use. Cross-sections, generally on a 100-ft. scale, are made at sufficiently close intervals to cover all details of structure. In many parts of the district a cross-section every 100 ft. is essential. It has become axiomatic among members of the department that the preparation and study of these cross-sections

is one of the most fruitful methods of using the geologic data. It may be stated without reservation that even those most accustomed to using maps and thinking in terms of three dimensions seldom fail to profit by the use of cross-sections. Many an unexpected orebody has been found through their assistance. They are too seldom employed in general.

In order to transmit to the proper officers the geologic conclusions reached, a system of 'recommendation sheets' is employed. These sheets are made out by each geologist as he reaches his conclusions. They carry the following information: mine, level, description of recommended work, object of recommended work, approximate distance to be run, date of recommendation, result (to be filled in later). The recommendations of the subordinate geologists are submitted to Messrs. Sales or Linforth for approval, and if endorsed, are forwarded to the mine-foremen for execution. Duplicate copies are filed for the information or action of the general superintendent. It has been found desirable to keep each foreman supplied with a large number of recommendations for each working level, in order that he may carry out the suggested work at the time most convenient to his general operations. Recommendations requiring immediate action are appropriately marked.

CONCLUSIONS. This outline covers the routine work of the Anaconda Geological Department. I have purposely emphasized those features in which I believe it to excel—for instance, the close co-operation with the men in the mines, the accuracy and detail of the notes taken, and the concentration of attention upon the structure of the ground. Its excellence in these lines may be attributed both to the special problems of Butte geology and to the good leadership and direction which have solved them.

The problems which other mines present to the geologist are not always the same as those of Butte. In some districts mining operations depend less upon structure, and more upon such matters as the genesis of the ore and its association with certain rocks. But the correct interpretation of these points cannot be made without the preliminary work of thorough and detailed mapping of the veins, rocks, and faults. From this structural work alone can the succession of geologic events which have created and localized an orebody be worked out in the proper sequence, and upon this knowledge alone can underground prospecting and development be successfully conducted. With the recent great and justified expansion of the use of the microscope in geological study it is perhaps well that conditions in Butte have combined to prevent this from resulting in a neglect of overalls and pick as essential tools of the mining geologist.

JAPAN has forged ahead to leading position among the foreign countries using American copper, a total of 117,354,241 lb. having been exported there during the nine months ended March 31. This is all the more interesting when it is realized that not a single pound was sent to Japan in the corresponding period last year.

Proceedings Against Minerals Separation Before the Federal Trade Commission

The calling of a former Federal Trade Commission Examiner to the witness-stand to inquire into his present relations with the Minerals Separation interests, his admission of visits (for purposes undisclosed) to the offices of both Minerals Separation North American Corporation and A. A. Cook, its counsel, since the commencement of the hearings, and statements by the Government prosecutor contradicting the witness, featured the resumed hearings of this case in New York on May third.

After the introduction of numerous exhibits in evidence on May third and fourth, Gaylord R. Hawkins, the Government prosecutor, upon completing a further examination of the president of Minerals Separation North American Corporation, startled those present by calling to the witness-stand Henry I. Foster, who was one of the Commission's original investigators of the Minerals Separation companies. Foster left the Commission on April 14, but has been a regular attendant at the hearings since then, at nobody's request, he said, but "merely as a visitor". The prosecutor's questions brought out admissions of visits by the witness to the Minerals Separation North American Corporation offices, as well as to the office of its attorney, but these visits "were not in connection with this case", according to the witness.

Foster denied that he was now employed by the North American Corporation or its counsel.

Mr. Hawkins asked the witness if he had not said that the income of the North American Corporation for the last year had been fourteen million dollars. This question stirred North American Corporation's counsel, as had all previous inquiries into the financial affairs of his clients. "I object to that as incompetent, irrelevant, and immaterial, hearsay of the most objectionable kind or character." The question was allowed, and Foster denied making such a statement. "He said it, all right," commented the prosecutor.

"What information have you, Mr. Cook, regarding the records of the Federal Trade Commission?" asked the prosecutor. "I have never seen them," replied Cook. This answer caused Mr. Hawkins to probe further. "Have you received any information, directly or indirectly, from anyone, as regards what these records and files of the Federal Trade Commission contain with respect to this case?" To this Cook answered, "I have received no information from anyone connected with the Federal Trade Commission as to what the records contain. I have no recollection of having been told by anybody what the records contain," and proceeded to explain that his remark to the Examiner had been based on inferences he had drawn from circumstances surrounding the case.

Mr. Cook, while he did not reveal the subject matter

of Foster's visits to his and to North American Corporation's offices, flatly denied the employment of Foster by him or his client.

A letter written by John Ballot, president of North American Corporation, to his counsel in 1918 was introduced in evidence by the respondents, and it refers, among other things, to the "enormous benefits derived from the unlicensed use of our process", and to "the enormous profits derived by them from the illegal use of our patents." Such profits, of course, being made by alleged infringers, were not reduced by the payment of the royalties exacted by North American Corporation. Some correspondence introduced by the Government is enlightening on this subject.

"We should like to make arrangements with your Company to use the Minerals Separation Company's process, if it can be done on the basis of the flotation concentrates produced," reads a letter from a prospective licensee. This was answered by North American Corporation, quoting their royalty-rates. The prospective licensee was prompt in his reply. "A license to use your process under the terms stated would be of no value to us." "If a more favorable basis for royalties cannot be had we shall be obliged to discontinue consideration of your process." And later, "A royalty on the mill-heads would amount to more than the net value of the concentrate produced. If you could give us a reasonable royalty based upon the flotation concentrates produced we would be willing to contract with you." The last word from this prospective licensee is brief but pointed. "The experiments were discontinued about the first of the year and since the apparatus has been dismantled and removed from the building."

Another company which had been experimenting with the process, assisted by a North American Corporation engineer, wrote as follows:

"The situation is that, as it is at present operated, the plant is not successful in any large way, and if we were to continue with our present indifferent results and were to pay your royalty in addition, we might almost as well suspend operation."

And on the subject of the demand of North American for double royalties on material treated during the experimental period, as "the unlicensed use of flotation":

"Your proposal acceptable except for the demand for past royalty. This work has been so unsuccessful to date that I wish you would waive this claim or make it subject to the complete success of the experimental work now proposed."

The chief engineer then took the matter up with the president, and advised the company of a lump sum that would be acceptable in full settlement. This "very large figure for settlement appalled" the company (which had

already been licensed—and they wrote:

"Had I known or realized that that accrued penalty was to hang over the head of the company, I should have dropped the matter where it was rather than go into the experimental work proposed with the outcome in doubt; and in that telegram I said that any such back royalties would be contingent upon highly favorable results. The Malmros work and the expenses incident thereto ran to a large figure, and the results were not gratifying and certainly in no degree commensurate with what I hoped we might get by reason of your laboratory tests, which indicated the possibility of trace tailings." . . . "We then tried faithfully under Mr. Malmros (the Minerals Separation engineer) to make a success. Our outlay direct for his per diem and expense was \$650; the collateral expense was at least \$200 in addition. Had you refused point blank to waive past royalties, almost certainly we would have saved these charges and dropped the work. As it was we went ahead and paid for work the successful outcome of which was a matter of common interest.

"A point that hurts me is that you reported tailings assays of trace and 20 cents (notation above), and this possibly led me on. Yet when I put up these figures to Mr. Malmros as a goal, he discounted them as mere laboratory results not to be obtained in practice. I had relied on them."

In a letter to North American, E. H. Nutter, the company's chief engineer, discussed the subject of royalty rates with refreshing frankness. "I know your views on the royalty question," he said, "but here is a case where, if we charge them an all-round royalty on all of their operations using flotation of say 10c. a ton or a royalty that would amount to this charge, it is I think all the traffic should bear. I am becoming more and more convinced that our royalties are too high, and am getting together data which I think will show that we are losing out financially through charging a royalty which is considered too high." And, further, "The only argument that I can see," continued Mr. Nutter, "is that by maintaining our present position we can hold the Butte & Superior company up for more than we otherwise might, but this, again, is not certain in my mind, as I understand the law is very definite that all of the profits of infringement belong to the patent owner and that our scale of royalties to non-infringers will not be considered."

In the same letter, Mr. Nutter discussed the experiments of United States Smelting, Refining & Mining Co. with flotation at various mines. He reported that at Pachuca "they figured that they could make about \$14,000 per month operating profit from the use of flotation, not counting royalty, but out of this they would have to amortize their smelting-plant and the charging over to flotation. The royalty would take all of this, and they would not make any profit at all from the charge; and he stated that they had stopped all investigations of flotation on this ore after receiving our royalty schedule." At Needles only one-sixteenth of their products was obtained by flotation, and "at normal metal prices their profit would not amount to the royalty

we are asking of them, and they would scrap their whole plant there."

Just why the North American Corporation was formed, and what interests control it were disclosed in correspondence introduced by the Government between (1913) Ltd. and British Treasury officials in 1916. One paragraph reads as follows:

"The profit-earning capacity of the company is very great, and every effort should be made to develop it to its full extent and to preserve the process for its British shareholders. The company's position at present is that it has to defend its extremely valuable property against the assaults of the larger portion of the powerful American mining interests whose avarice will not permit any scruples to stand in their way, if by any chance they can crush the company, in spite of the enormous profits they are making or will continue to make even after paying the moderate royalty demanded. . . . By transferring the company to America on the lines proposed, the shares would still continue to belong to and be held by exactly the same shareholders now on the British register, and in exactly the same proportion, except that 7% of the whole share capital will be contributed by shareholders and used to cancel or commute the payment to the Agents of 10% of the gross income, as fully explained above and in the Agreement of 4th August, 1916."

That the process has been "preserved to its British shareholders" is confirmed by an inspection of the stockholders' list of the North American Corporation introduced in evidence. Except for the several alien stockholders residing in the United States and stock held by the Alien Property Custodian there are but five American addresses out of some two hundred, all the rest being foreign, and these own but 10,500 of the 500,000 shares!

MINERALS SEPARATION'S VIEW OF AMERICAN JUSTICE

"In one notable instance, at the hearing by the San Francisco Appeal Court of an appeal against the company, the opposing counsel actually told the Court that the company was a foreign corporation and alleged that it was trying to exact a tribute from the United States mining industry 'equal to the National Debt'. The Court, no doubt, influenced by this consideration, decided against the British company, but that decision has since been called up for revision by the Supreme Court in Washington, hence the need for expediting the transfer to American registration to assist as far as possible in counteracting any prejudice which may exist or be insinuated against the British company at the final hearing of this and two other important actions pending at present before the Federal Courts of the United States. . . . If the transfer of the English company to America is not soon allowed, the existing hostility in America against the company will not only increase, but as has already occurred may again be used to prejudice the company's cause in the three actions at present before the Federal Courts of the United States."

The hearings in New York adjourned on May 5. They will be resumed sometime after the first of June at such place as may be decided upon by the Commission.

Minerals Separation v. Miami Copper Company

Affidavit of Theodore J. Hoover

STATE OF CALIFORNIA)
County of Santa Clara) ss.

BE IT REMEMBERED that on this Thirteenth day of May, A. D. 1920, personally appeared before me, C. E. JORDAN, a Notary Public of the State of California, THEODORE J. HOOVER, known to me personally to be such, who being by me first duly qualified according to law, deposes and says:—

I am a Mining Engineer by profession, having graduated at Stanford University in the year 1901. Since my graduation I have practiced my profession and have acted as superintendent and manager of mines and mining properties, and also as general consultant, director and officer of various mining companies. In April of 1919 I was appointed Professor of Mining and Metallurgy at Stanford University, and since September of 1919 have been in charge of the Department of Mining and Metallurgy at Stanford University.

In the year 1906 I was engaged as General Manager by Minerals Separation, Limited, the above-named defendant.

At that time (1906) Minerals Separation, Limited, was the owner by assignment of the English Patent No. 7803 of 1905, granted to Messrs. Henry L. Sulman, Hugh F. K. Picard and John Ballot. This patent was for Improvements in Ore Concentration, and was then generally spoken of by the officers, engineers and agents of the said company as "the oleic-acid-froth patent" or "the frothing patent", to distinguish it from the Cattermole "granulation" process owned by the same company; and at a later date was referred to as "the agitation-froth patent" or "the Minerals Separation process patent". This patent is the English equivalent of the United States Patent No. 835,120, granted to the same persons, which has been spoken of in this litigation as the first patent in suit. The United States Patent No. 835,120 was not assigned to Minerals Separation, Limited, by the patentees until December 1909.

At the time of my entry into the service of Minerals Separation, Limited, Henry L. Sulman and Hugh F. K. Picard were acting as Consulting Metallurgists of Minerals Separation, Limited, and so continued to act, certainly until 1916; and, so far as I am informed, are still so acting. Shortly after entering the service of Minerals Separation, Limited, I was informed by John Ballot, who was at that time President of Minerals Separation, Limited, that I could inform myself as to the technical and scientific side of the flotation processes by having recourse to Messrs. Sulman and Picard; that Messrs. Sulman and Picard had prepared a treatise on "The Theory of Concentration Processes Involving Surface Tension", and that in all probability I would be permitted to read this treatise if I approached Messrs.

Sulman and Picard upon the subject; that the treatise was a full and complete one developing the whole subject in a scientific and satisfactory manner.

In due season thereafter I sought out Messrs. Sulman and Picard in this connection and discussed broadly the technical and scientific aspects of flotation processes. These discussions between myself and Messrs. Sulman and Picard continued throughout the term of my engagement with Minerals Separation, Limited. At one of the first interviews on this subject with Messrs. Sulman and Picard the existence of the treatise, above referred to, was alluded to by Mr. Sulman, and a copy of this treatise was handed to me by Mr. Sulman some time during the first half of 1907. No request has ever been made by either Messrs. Sulman and Picard, or by any other person, for its return, and it remained continuously in my personal possession until December 27th, 1919, from which date Mr. John F. Neary has also had access to it, under circumstances which I shall describe in a moment.

During the four years of my connection with Minerals Separation, Limited, and subsequently, I have read this treatise many times and am thoroughly familiar with the views of the authors as expressed therein.

I severed my connection with Minerals Separation, Limited, in December of 1910, and since that date have not been in their service or employ in any capacity.

In August of 1919 I was interviewed by Mr. John F. Neary, counsel for the Miami Copper Company, with relation to the early history and development of flotation processes. As a result of this and subsequent interviews, I have carefully examined the Appeal Record in this case, as well as the record of the proceedings before the Master on the accounting. From such examination of the record I learned that the present contentions of the complainant therein as to the scope of United States Patent No. 835,120 are so entirely opposed to the statements of two of the patentees as contained in the treatise, above referred to, as to amount, in my opinion, to an attempt to perpetrate a fraud on the court and to impose an unwarranted and unjustifiable burden upon the mining industry of the country.

The treatise referred to fully develops the knowledge of said Sulman and Picard, and their understanding of the art prior to the date of application for the first patent in suit, and their statement of such prior art is wholly inconsistent with the position for which their assignee, Minerals Separation, Limited, is now contending in this case.

I then sought and received legal opinion as to my obligation under the contract of employment with Minerals Separation, Limited, above referred to, and I have been advised and I believe that I am free from any duty to remain silent as to the existence and contents of said treatise under the circumstances of this case, particu-

larly as I believe that the rights of the public are also involved.

The Miami Copper Company, the defendant in the original suit, complainant in this proceeding, its officers, agents, attorneys or servants, did not know, through me or through others as far as I know, of the contents of this treatise until October of 1919, when the treatise was submitted to counsel for inspection and opinion as to its competency and materiality as a matter of evidence in said litigation. Owing to the fact that I reside and am actively engaged in teaching at Stanford University, California, and that counsel and the officers of the Miami Copper Company reside and are engaged in business in and about New York City, the said treatise, entitled "The Theory of Concentration Processes Involving Surface Tension", was by me deposited in a safe in the New York Produce Exchange Safe Deposit & Storage Company, on December 27th, 1919, Mr. John F. Neary and myself being the only persons who were given the right of access thereto. I happened to be in New York at that time and was about to return to San Francisco; I was then still considering the propriety of permitting the use of this treatise in this case and deposited it in the safe, and gave Mr. Neary right of access thereto, in order that it might readily be obtained in the event that I finally determined that it might properly be used. I so determined on April 12th, 1920, and at that time authorized Mr. Neary to use the treatise.

The said treatise has been in my possession, and under my sole control, continuously from the date of its receipt by me from Mr. Sulman, as hereinabove described, until it was placed in the safe as aforesaid; no part of said treatise was, during my possession, abstracted or changed in any respect, and nothing was added thereto; the said treatise being, when placed in said safe, in exactly the condition in which it was at the date of its delivery to me, except insofar as the elements, time and the ordinary wear and tear in its perusal may have resulted in dimming and discoloration.

THEODORE J. HOOVER.

Sworn to and subscribed before
me, this Thirteenth day of
May, A. D. 1920.

C. E. JORDAN.

[NOTARIAL SEAL]

Affidavit of William S. Stevens

STATE OF ILLINOIS)
County of Cook.) ss

BE IT REMEMBERED that, on this seventeenth day of May, 1920, personally appeared before me R. R. McCormick, a notary public of the State of Illinois, WILLIAM S. STEVENS, known to me personally to be such, who, being by me first duly qualified according to law, deposes and says:

I am 36 years of age and reside in Chicago, Ill.

I am now in the employ of the Sherwin-Williams Co., manufacturers of paints, and have been so employed since the year 1910. My headquarters are at Pullman

Station, Chicago, Illinois. I am a Metallurgical and Chemical Engineer and an Associate of the Institution of Mining and Metallurgy.

In the year 1906, I entered the employ of Minerals Separation, Limited, a Corporation of Great Britain, and continued in such employ until September 1910. During the year 1907, I was acting as a laboratory assistant, working under the general directions of H. L. Sulman and H. F. K. Picard, Consulting Metallurgists of said Minerals Separation, Limited. During the month of December 1907, at the direction of said Sulman and Picard, I conducted a series of tests in London, England, on the use of centrifugal pumps as the agitating means to produce the condition of aeration considered necessary in the process of the English Patent, No. 7803 of 1905, issued to Sulman, Picard and Ballot (the English equivalent of the U. S. Patent No. 835120, issued to the same parties). In these tests a Gabbett mixer, such as those shown in Complainant's Exhibit, Sulman Drawing, accompanying Report, May 3rd 1905, appearing at page 85, Volume IV, Appeal Record, in the case of Miami Copper Company *versus* Minerals Separation, Limited, was used for mixing the ore, water and acid. The pulp so mixed was delivered from the Gabbett into a funnel feeding the centrifugal pump. Into this funnel was fed oleic soap solution containing oleic acid in an amount equivalent to two-tenths per cent. on the ore. The pump delivered the oiled pulp to a following spitzkasten, wherein little or no froth was obtained as a result of such treatment in the centrifugal pump. Using the same procedure and the same apparatus, an experiment was conducted in which air was introduced into the centrifugal pump with the pulp. No improved results were obtained in this experiment. Subsequently a second pump was installed, following the first pump, and the same procedure was carried out, as before, the pulp passing through the two pumps after the addition of the oleic soap solution in the funnel feeding the first pump. There was no substantial difference in the result, by reason of the use of the additional pump.

This series of experiments covered all possible variations of treatment with the apparatus above described, and as the result of these tests, the said Sulman and Picard stated to me that they had concluded that the use of centrifugal pumps did not result in the production of the aeration considered essential in such process for the production of a froth, and instructed me to discontinue the use of the centrifugal pump as an agitator in the operation of said process.

WILLIAM SIDNEY STEVENS.

Sworn to and subscribed
to before me, this 18th
day of May 1920.

R. R. McCORMICK.

[NOTARIAL SEAL]

SALES OF COPPER, including both foreign and domestic transactions during May, totaled 62,000,000 lb., compared with 101,000,000 in April and 320,000,000 in March.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

NUMEROUS FLOTATION PLANTS NEAR PRESCOTT.

PRESCOTT.—The oil-flotation process is highly successful in the treatment of ores in Yavapai county. There are five mills using the process, treating silver-gold ores, namely: the L. T. S. custom mill, situated four miles south of Turkey; the Pocahontas mill, two miles southeast of Mayer; the Anderson-Birch mill, two miles west of Humboldt; the Black Diamond, at Walker; and the Monte Cristo on Groom creek, eight miles south of Prescott. The ore treated varies from a simple gold-silver product such as the Monte Cristo to a complex ore of copper, gold, silver, lead, and zinc such as is found at the Pocahontas mine. The precious metals predominate. Two mills are using the process on copper ore: the Arizona Binghamton at Stoddard, five miles east of Mayer, and at the Consolidated Arizona Smelter Co.'s plant at Humboldt. The ore treated is a chalcopryite copper. Several old mills are being converted into flotation plants and one new mill, the Abe Lincoln, north of Wickenburg, is about to start with a daily capacity of 100 tons. The Peak Silver Mining Co., recently organized, proposes to install the process in two old mills on Groom creek. There are many old properties south of Prescott, as far as Tip Top, 65 miles, that were worked many years ago for the free gold and silver. These afford excellent opportunities with the flotation process. There are possibly 25 old amalgamation mills that could be converted into the newer flotation units.

The Peak Silver Mining company has opened an old vein of high-grade gold-silver ore in the Black Horse mine, one of six old properties recently taken over by the company. The vein is three feet wide, the ore valued at from \$30 to \$154. Three earloads of high-grade ore were shipped from the mine 30 years ago. J. E. Pierson of Prescott is general manager. The company plans extensive development for all six properties. An important strike of copper has been made at 980 ft. in the United Arizona mine, 16 miles west of Cordes. The shaft penetrated a vein 14 ft. wide said to average 25% copper. It is considered one of the richest discoveries made in the county. C. J. Bendewald, of Mayer, is the general manager. The mine is to obtain electric power from the Arizona Power Co.'s wire which passes close by. Plans have been completed for a 100-ton oil-flotation plant at the Silver Belt mine, two miles west of Humboldt. Regular shipments of ore are made to the Humboldt smelter. H. H. Burt, of Prescott, is the consulting engineer.

BISBEE.—The Shattuck Arizona Copper Co. reports for the quarter ended March 31, total receipts of \$14,902 and net income after depreciation, etc., of \$55,740. Metals recovered from copper ores during the quarter were: copper, 1,002,292 lb.; gold, 215 oz.; silver, 26,332 oz. Metals recovered from lead concentrates were: lead, 1,902,791 lb.; gold, 934 oz.; silver, 51,198 oz. Metals recovered from lead ores were: lead, 17,948 lb.; gold, 7 oz.; silver, 396 oz. The net income is equal to nearly 16c. per share of stock for the quarter.

JEROME.—The tunnel of the Shea Copper Co. has been advanced 725 ft. and shows the vein to have a width of 12 ft., 30 in. of which is ore. Samples show an average value of \$30 per ton in silver and copper. Preparations for stoping and shipping are to be made immediately. It is reported that the United Verde Extension Mining Co. has taken an option on the Chief property, which adjoins the Shea.

OATMAN.—The report of operations of the United Eastern Mining Co. for the first four months of the present year shows that 38,210 tons of ore was milled with a gross value of \$752,631 and a bullion recovery of \$727,686. Operating costs were \$317,515, leaving a net operating income of \$410,171.

TUCSON.—A strike of high-grade silver ore has been made on the property of the Sherwood Copper Co., which is located in Comabobi district. The ore was opened on the 145-ft. level while drifting on a stringer. It is said the vein contains native wire silver, is three feet wide, and assays as high as \$700 to \$800 per ton in silver. High-grade ore is now being sacked and shipped. The St. Louis mine at Greaterville is now being operated, having been taken over by the Liberty Silver Mines Co. The old St. Louis shaft is being sunk to greater depth, having now reached the 145-ft. level. At this point the vein has widened considerably. A compressor and other necessary machinery have been installed to carry on development.

COLORADO

DIVIDENDS FROM CRIPPLE CREEK MINES.

CRIPPLE CREEK.—Interest in the district is now centered in the north end, where diamond-drill exploration to determine presence of eruptive rocks under the granite capping is shortly to commence. Equipment has already arrived and has been unloaded at the Gillet awaiting transportation to the camp to be established on the Wild ranch in the saddle between Tenderfoot hill and Rhyo-

like Mountain. The point for the first hole was selected last week by George H. Stahl, general manager for the Vindicator Consolidated Mines Co., W. R. Ryan, superintendent, and Harry W. Robinson, the drilling contractor. No attempt will be made to find ore or mineralized dikes. The first and possibly the second drill-holes will, it is expected, determine if eruptive is present under the granite. If the eruptive is found at an economical depth a three-compartment shaft will be sunk, and diamond drilling will again be resorted to for further prospecting.

With the payment, on June 10, of the monthly dividend of \$30,000 the Golden Cycle Mining & Reduction Co. announced that future distributions will be quarterly as earnings warrant. Stockholders of the Cresson Consolidated on June 10 were advised that net earnings for the months of February, March, and April totaled \$160,521. The company, as of May 31, had cash in bank amounting to \$276,121, and unsettled ore at mill of an estimated value of \$10,000. Ore-reserves as of May 1, 1920, have an estimated value of \$1,523,985.

IDAHO SPRINGS.—Vacant mining ground near here was located only last week and the location certificate for the Virginia B. lode, 350 by 1500 ft., was filed for record by W. J. Baker, manager for the recently organized Metals Mining & Leasing Co., operating the Jenny Lind group. The claim, named after his daughter, lies along the line of the Big Five tunnel. A shaft was sunk below the wash, and three feet of vein matter exposed carries some silver. Mr. Baker proposes to cross-cut and search for the vein from the Big Five tunnel, that cuts the claim at a depth approximately 2000 feet.

SILVERTON.—The Gold King Extension Mines Co. has resumed work in its stamp-mill with 40 stamps dropping and will increase to full capacity of 80 stamps as soon as men can be secured at the mine and mill. The shipment of concentrate to the smelter is going on and three cars daily are leaving the property. With the full force working, 300 tons of ore will be required by the mill.

OURAY.—Boston capital has become interested in development of the Superior and Bonanza King properties, with E. H. Manhire, of Montrose, one of the former owners, in charge. The Superior and Bonanza King tunnel will be extended to cut veins exposed in surface workings and a force of miners will be employed. A compressor, an electric motor, and other mine equipment is awaiting completion of a bridge and clearing of the road to the Des Ouray group, where they will be installed by the Eurades Mining Co. A contract has been let for 100,000 ft. of lumber, and buildings are under construction. Miners have been engaged and development started.

TELLURIDE.—Ore shipments from Telluride for May totaled 90 cars; 50 cars of concentrate from the Smuggler mill and 40 cars from the Smuggler Union. The Valley View mill at Matterhorn is awaiting machinery. The Valley View Leasing Co. continues mining ore and has large tonnage held in reserve for the mill. Exploitation of the Chris Martinson group of claims near Placer-

ville for Vanadium is in progress and shipments will shortly be made to the plant of the American Vanadium company, at Vanadium, formerly owned by the Primos Chemical Company.

MICHIGAN

BOND ISSUE FOR HANCOCK CONSOLIDATED.

Houghton.—Shareholders of the Hancock Consolidated company will meet on June 16, when it is expected they will authorize a bond issue of half a million dollars. This will cover the outstanding indebtedness and provide for future development work. The present operating corporation has conducted a rather complete development plan for the past year. The results, to date, are not satisfactory. Illustrating the amount of money that may be expended in search for profitable copper ground the Hancock Consolidated has 100,000 shares and the shareholders have paid in the \$25 par value, so that further capital must come from bond-sales or a re-organization of the company, which is working under the Michigan law. Hancock territory adjoins the Quincy and includes a block of St. Mary's Mineral Land Co. holdings. In Civil War days the mine was run by Edward Ryan and a considerable sum was expended in an effort to open a profitable producer. John D. Ryan, head of the Anaconda, Inspiration, and other properties, was largely instrumental in financing the present company, in an effort to assist the town of his youth with another industry. A year ago the company sold to the Quincy 140 acres of mineral land for \$251,523, thereby reducing its indebtedness.

The coal shortage in the Lake Superior district has hurt the smaller mines. The Franklin has been compelled to suspend all operations except the pumping and has just coal enough to do that for two weeks. Franklin has been opening some good looking territory north of the 39th level. The lateral shows material richer than 1% for 600 ft. Raises are started every 50 ft. and as far as they have gone are in good ore. To the south, on the same level, they have started to drift in good 'rock'. A winze on line with the shaft, which is in the foot-wall, will be started at once to provide ventilation and a place to drop the ore for hoisting purposes.

There is much interest in the continued opening of good ore in the Seneca. The shaft is nearing the 5th level and the raise to the 4th is well under way. On the 3rd and 4th levels the drifts continue in good ore, except for one bunch of poor quality that was met 230 ft. south on the 3rd. At this writing the miners are out of that again and in a grade of ore which is better than anything so far encountered in the Seneca development of the Kearsarge lode. Shipments to the mill include a small amount from the stock-pile but most of it comes from present underground developments. At the Gratiot, under option to the Seneca company, the 15th level drift south is in 260 ft. in fair looking material.

N. D. Hansen and L. Suverkrop are conducting a series of experiments at the Michigan College of Mines. They are working on a plan for the extraction of oil from stumpage on the upper peninsula. The oil is to be used

in the operation of the flotation process in local metallurgical plants. Soft wood stumpage is preferable but any will do. A chemical plant in Houghton already is planned. The stumpage has long been a serious agricultural problem.

Almceek is making a practice of replacing timber sets in the steeper parts of the mine with concrete sets. A year ago No. 4 shaft was shut-down for three months to permit extended operations of this nature. This shaft today is producing satisfactory ore in large quantity. Openings both north and south of the 20th and 21st levels are in particularly good ground. The 14th, 15th, 16th, 17th, and 18th levels now are being run only to the north.

MONTANA

WORK ON CORBIN AND BUTTE & BALLAKLAVA TO COMMENCE.

LIBBY.—The concentrator at the Lukens-Hazel mine is rapidly nearing completion. A crew of 32 men has already completed the housing for the mill, and the crusher is in place. Most of the equipment to be constructed on the ground has been completed.

HELENA.—The Sunset mine, situated about one mile west of the Free Coinage mine, is to be re-opened after lying dormant for a period of 25 years. The mine will be developed by a system of tunnels, one of which has already been driven 120 ft. The main orebody is expected to be reached within 30 ft. Samples taken from the property assay 55 oz. of silver per ton.

WICKES.—A two-foot vein of high-grade silver ore has been discovered in the Minal mine in tunnel No. 4, said to be the richest ore ever found in the district.

Basin.—J. Asher Cowan, of Salt Lake City, has organized a company to exploit the Silver Trail property, which consists of five claims about three miles from the Basin. Three and one-half tons of ore from surface fissures averaged 112 oz. silver and \$9 in gold. Fourteen tons show an average assay of 36 oz. silver and \$3 in gold. A 200-ft. adit has already been driven.

BUTTE.—The Butte & Ballaklava property has passed under the control of the Silver Butte Mines Co., a Delaware corporation, which has also secured control of the Corbin-Copper King Co. at Corbin. The Butte & Ballaklava is situated on Butte hill and adjoins the Modoc and Modoc Extension on the south. The property has a 1600-ft. three-compartment shaft and a winze extending from the 1600 to the 1800-ft. level. Lack of funds has held back further development. There is an outstanding bond issue of 177,000 shares. Operations on both Corbin and Butte properties will soon begin.

Sinking has been resumed at the Butte & Plutus. The shaft will be extended to the 400-ft. level where a cross-cut will be started toward the Norwich vein. Unless water is reached at this point, the shaft will be continued to 600 ft., where the hoisting capacity of the present

plant will be reached. Three shifts are at work. The work already done on the claim has disclosed the Plutus lead on the 100 ft. level and in the shaft 150 ft. from the surface. John R. Moyle is president of the company.

The Mike Horse mine in the Big Blackfoot region is operated by the Sterling Mining & Milling Co. Tunnel No. 3 has been driven 800 ft., uncovering a good vein of milling ore. Tunnel No. 1 shows 6 ft. of ore, while in tunnel No. 2 excellent milling ore is being passed through. In three stops on this level, the vein matter is from 6 to 12 ft. wide.

NEMHART.—The mines of this district are still down. In view of the sharp decline in the silver market, it is more than likely that no attempt will be made to resume operations at present.

Prior to the shut-down of the mines in this district, the Flohart Silver Mines Co. was making excellent progress in the development of the property. Air-lines

PRECIPITATING COPPER LEACHED FROM OLD DUMPS AT BUTTE

were being put at all points in the mine, much of the old timber work was being replaced, and all of the dangerous workings were being made safe. In tunnel No. 1 the Florence and Preston veins were opened and showed small streaks of ore.

NEVADA

CAVING SYSTEM ADOPTED BY UNITED COMSTOCK MINES CO.

VIRGINIA CITY.—The 2,200,000 tons of ore assaying \$10 to \$15 that is estimated to be blocked out from the surface to the 400-ft. level of the Imperial shaft of the United Comstock Mines Co. is to be mined by block-caving into branched chutes. The ore is in a block 500 ft. long and 75 to 100 ft. wide. A 10,000-ft. tunnel that will be used as a haulageway will be driven under this block, sub-levels will be opened from inclined raises and short branch or 'finger' raises will be driven from the main raises. Under-cutting and caving will be used to draw the ore by blasting between the sub-levels. This is a low-cost system used by the Inspiration at Miami, Ohio at Bingham, Nevada at Ely, and other companies

containing ore that breaks easily. The tunnel will be at a depth of 100 to 700 ft., as it is extended through the various claims and it will be driven rapidly by starting work simultaneously from four old shafts and the surface. The company, according to an official statement, has \$2,500,000 in the treasury and the plans include the erection of a 100-ton cyanide mill. The company controls a large acreage extending for 10,000 ft. along the Comstock lode and this will be prospected after work has been started in the Imperial. The companies taken over by the United Comstock are the Alpha, Imperial, Confidence, Challenge, Yellow Jacket, Crown Point, Belcher, Kentuck, Segregated Belcher, Globe, and Knickerbocker.

GOLDFIELD.—Details of the agreement for the organization of the Goldfield Deep Mines Co. of Nevada show that included in the consolidation is all the property, including cash, of the C. O. D., Merger, Atlanta, Blue Bull, Goldfield Combination, a defunct Washington corporation, and the Golconda, Mammoth, and Red Boy claims of the Goldfield Consolidated. The Combination is to be paid \$12,500, or a stockholder, instead of his share of this sum, may secure Deep Mines stock at one cent per share upon surrender of his stock to the Deep Mines. The C. O. D. has outstanding 2,941,200 shares, and no cash. C. O. D. stock may be exchanged share for share on payment of a one-cent assessment. The Consolidated, in exchange for the five claims, will receive 1,575,586 shares of Deep Mines and will pay out of the Consolidated treasury a one-cent assessment on this amount. The Merger has outstanding 5,966,000 shares and there is no cash in the treasury. Merger stock may be exchanged share for share on payment of one cent. The Atlanta has outstanding 4,288,156 shares and there is \$43,000 in the treasury. Atlanta stock may be exchanged share for share without the payment of an assessment. The Blue Bull has outstanding 1,500,000 shares and has \$14,000 in the treasury. Blue Bull stock also may be exchanged share for share without the payment of an assessment. The assessment will be delinquent not less than 40 days after the stockholders have been notified of the ratification of the contract with the new company. The Deep Mines is incorporated for 18,000,000 shares, par value five cents. The object of the organization of the Deep Mines is to provide funds for the sinking of a shaft to a possible depth of 3000 ft. and the exploration of the Consolidated-Florence vein where it enters the shale. Between Columbia and Indicator mountains there is a depression in the shale and the present plan is to sink a shaft through the shale and into the granite at the lowest point in the depression, which, according to Corrin Barnes, geologist for the Deep Mines, may be the source of some of the porphyry flows forming the present surface. Some of the richest ore-shoots in the Consolidated-Florence vein have been found at the shale-latitude contact in the Jumbo and Grizzly Bear. The Spearhead is prospecting this vein in the alaskite at a place where the latite and alaskite contact. Here the vein is composed of silicified alaskite,

quartz, and alunite, and low assays in gold are secured.

PIOCHE.—Shipping of lead-silver-gold ore has been started from the Hamburg, 10 miles from Pioche. The Hamburg is one of the oldest mines in the vicinity of Pioche and it is said that a total of \$200,000 worth of ore has been shipped at various times. The ore is coming from seams in low-grade material in drifts from a 130-ft. shaft and from old stopes. The ore is in beds in limestone and work was stopped several years ago when raises failed to find the continuation of a shoot thought to have been thrown upward by a fault. An inspection of the workings several months ago led to the opinion that the developed part of the vein is cut by two faults, one of which has been found, and the present work is being done to find and prospect beyond the second, where it is thought instead of the broken, low-grade ore now exposed, the vein will be found to have been little altered by the fault action. If there are good results from this work it is planned to resume sinking the shaft.

ROUND MOUNTAIN.—The report of the Fairview Round Mountain for the year ended December 31, 1919, shows there was mined and milled during the year 8692 tons of ore of a gross value of \$311,757. Bullion worth \$296,465 was produced with an extraction of 95.1%, or 2% more than in 1918. The gross value per ton of the ore treated was \$35.86 and the loss in tailing amounted to \$1.76, leaving a net value of \$34.10. The operating cost, exclusive of depreciation and depletion, was \$119.811, or \$13.78 per ton. Of this, \$22,023, or \$2.53 per ton, was for milling. Dividends amounting to \$134,665 were paid during the year.

MINA.—The station on the seventh level of the Simon Silver-Lead mine has been timbered; the skip-pocket, 20 ft. below the station, has been finished; the pumping station completed, and cross-cutting started to cut the downward extension of the orebodies developed on the fourth, fifth, and sixth levels. The cross-cut has entered heavily mineralized and highly silicified limestone entered heretofore in practically all drifts and cross-cuts before the ore was found. Ore has been reached in cross-cut No. 613 driven on the sixth level south-westerly to find the faulted segment of the ore thrown off by the west fault. A streak about one foot wide assayed 99.6 oz. silver, 7.4% lead, 10.5% zinc, and .80e. in gold. A check sample on the silver content returned 100.2 oz. silver and another sampling returned 66.7 oz. silver.

The framework for the new cyanide mill in course of erection by the Olympic Mines Co., capacity to be 65 tons per day, to use a counter-current decantation cyaniding process, has been completed. Two Fairbanks-Morse type 'Y' vertical-cylinder semi-Diesel engines have been bought. Machinery is being hauled from Mina to the property. The former mill was totally destroyed by fire last spring. The company recently bought from J. P. Nelson and associates the Loo mine following an examination by Fred Searles, geologist. According to an announcement by the management a large tonnage of gold ore of commercial grade has been developed in the Olympic and the Loo mines.

UTAH

PROGRESS IN CONSTRUCTION WORK ON THE CONCENTRATOR OF THE TINTIC STANDARD COMPANY.

ALTA.—Development and exploration of the orebody on the 100-ft. level of the Emma mine are proceeding steadily, according to George H. Dern, general manager. A number of well-defined faults, while not serious, have made the prospecting more difficult. At present, the work farthest along the strike of the bedding shows the orebody to be less disturbed. The important fact brought out by the work in the new orebody is that the ore occurs as a replacement of the Emma or Flagstaff limestone. Special importance is attached to this fact, because it is the same formation that contained the bonanza orebodies that were mined in the Flagstaff, Vallejo, and Emma mines in the '70s. The ore, as developed at present, extends more than 85 ft. from the point where it was cut at the Montezuma fault, has a width of approximately 30 ft., and is about seven feet thick. Approximately 1000 tons of ore is stored in the bins, on dumps, and underground awaiting shipment. The beginning of shipping will depend on the rapidity with which the snow melts and the wagon-roads get in such shape as to permit hauling to the railroad.

Suit to recover \$45,000, triple the value of ore alleged to have been secretly extracted from the Columbus No. 4 lode mining claim, was filed recently in the Third District court at Salt Lake City by the Wasatch Mines Co. against the Cabin Mining Co. The complaint alleges that the defendants began secretly taking out ore from the mentioned lode in July 1917, and continued to do so until mineral to the value of \$15,000 was taken. The Court is asked to give judgment in accord with the State mining law for thrice the value of the ore alleged to have been extracted from the plaintiff's property.

The Board of Directors of the Tar Baby Mining Co. re-elected J. Martin Matsen as president and general manager at the annual meeting held on June 7. Mr. Matsen reported that 800 ft. of work had been done during the fiscal year ended June 1, 1920, the last 410 ft. of which was in the Cardiff lime. This stratum is from 425 to 465 ft. thick. The lime is highly mineralized with pyrite and iron carbonate.

BINGHAM.—Practically all of the underground mining companies in this camp have adopted the plan of letting their work out under contract, and the majority of the superintendents are pleased with this system. One of the first companies to start this method was the Utah-Apex. Under this plan, the men get paid for the amount of work they do, and if they feel disposed to work nine or ten hours instead of a straight eight-hour shift, it is their privilege to do so. There is still a considerable shortage of labor, but lately a number of mining students and even local high-school boys have been going to work in the mines for the summer vacation.

TECOMA.—Work is progressing at the Tecoma Consolidated property, 2½ miles from this station. Ore-bins to furnish storage have been completed at the mine and loading station. The road has been put in excellent shape

for hauling by automobile trucks, and all details have been arranged so that capacity shipments may be started as soon as the plant of the Utah Zinc Co. at Murray is completed. This plant at present is 80% finished, and operations will be started about July 15. The main face of the Woodward tunnel is being driven to tap at depth the zinc orebody blocked out in the old workings by the Utah Zinc Co., and to prospect at depth all of the important fissures which form a network in the formation. At a distance of 675 ft. from the portal, a raise is being put up to furnish an outlet for the ore above. At the same point a drift is being driven north-west on a fissure

LOUISE MINE AT ALTA, UTAH

in which a good showing of silver-lead ore was cut by the main tunnel. Raising has been started at a point 850 ft. from the portal to furnish another connection with the upper workings.

PARK CITY.—An important strike has been made at the Park-Utah mine. In a cross-cut some three feet of good shipping ore is being followed, which has every appearance of being a persistent body. Streaks from 8 to 15 in., carrying 90 oz. of silver, are in the vein, with large quantities of milling ore. Ore shipments from this property will begin during June, as the Ontario tunnel is now being put in shape so that the ore can be taken to the shaft, hoisted to the 600-ft. level, and conveyed to the Ontario loading station.

EUREKA.—The volume of production at the majority of the mines here is reduced, owing to the fact that the

operators have asked the operators to cut down their shipments to 50% of normal. During the week ended June 5, a total of 137 cars of ore was shipped, as against 139 the previous week. The Chief Consolidated shipped 10 cars; Dragon, 23; Tintie Standard, 20; Grand Central, 8; Iron Blossom, 7; Iron King, 7; Mammoth, 6; Eagle & Blue Bell, 5; Victoria, 5; Centennial-Eureka, 4; Seranton, 1; Gemini, 3; Swansea, 2; Colorado, 2; Bullion Beck, 2; Sunbeam, Alaska, and Ridge & Valley, each 1.

Rapid progress is being made by the Tintie Standard Mining Co. in the construction of its new concentrator at Warm creek. With a force of more than 200 men at work, it is expected that the mill will be ready by early fall. A spur-track, nearly a mile long, leads from the main track of the Denver & Rio Grande railroad to the mill. The boarding and bunk-houses, modern in every particular, are about completed. Two large transformers are now being placed in position on the hillside and it will be a matter of only a short time until electric power will be available for operation of the tram, now under construction, to elevate supplies to the mill-site. The mill will eventually have a capacity of 1000 tons per day; a large tank, of California redwood, is being constructed above the mill-site, to assure an ample water-supply.

Officials of the Eureka Hill Mining Co. have made arrangements to lease a large block of ground to a Salt Lake company which has been organized by L. E. Riter and associates. The ground to be covered by the lease is at the south end of the Eureka Hill holdings, adjoining the Centennial-Eureka property. The exploration work will be handled through the Centennial-Eureka workings. Some of the best ore that has ever been produced in this district came from the south end of the Eureka Hill tract, and there is a possibility of the lessees opening valuable deposits. This part of the Eureka Hill's property has been inactive for some years, owing to the dismantling of the hoisting plant.

WISCONSIN

REVIEW FOR MAY.

The delays, following the railway strike, incident to the marketing of ore were brought out forcibly in the case of the Block-House Mining Co., of Platteville. Some high-grade zinc ore sold to the Mineral Point Zinc Co. was a month on a haul considerably under 300 miles. The congestion in the East reached such proportions that a solid train load of slab-zinc consigned to Eastern consumers was lost track of entirely. High-grade refinery product was bid-in at \$53 per ton, the first week in May. By the middle of the month such ore as had been sold on contract had reached smelters and no quotations were made public. Diligent inquiry found a shipment of high-grade prime Western ore the third week, the base offering on which was \$49.25 per ton. The closing days of the month found high-grade shipments of zinc ore on a range of prices running from \$47 to \$49 per ton; second grades, \$43.50 to \$45. At the latter price one of

the leading operators of the field declared production could not be maintained at this level and that no attempt would be made to reach market with ore available for delivery. Low-grade zinc-ore producers selling on open-market quotations met with little or no consideration the greater part of the month. Offerings fell to a point no longer inviting and great stocks of milled concentrate accumulated at all points, the total in the field probably exceeding 10,000 tons.

Lead-ore producers suffered in like manner, although prices remained firmer and demand for lead ore continued steady and good. Starting at \$110, the price broke early in the month and receded to \$100 per ton, base 80% metal content. Production, contingent upon the volume of wet milling, in this field, was light and the reserve in the field was trimmed down to about 500 tons. Shipments for the month were fair, the idea gaining ground that less than \$100 would be paid and that it would not be profitable to hold longer. While prices remain high many small firms diligently seek sub-leases on mining lands to root over shallow diggings and surface workings but no appreciable quantity of lead ore has been obtained in this manner. The ore sold during May came from the large zinc-producing mines and the supply of lead ore from this field will be obtained in this manner no matter what the status of the lead-ore markets. At times some little competition seemed to develop among buyers, but for the greater part of the month the Federal Lead Co. seemed to set the pace on bids, with the American Zinc & Lead Smelting Co. a close contender.

The production of carbonate zinc ore, in the northern part of the field, received impetus through operations of small independent concerns selling in the open market, the range of prices going from \$35 to \$40 per ton, base 40% zinc assays. The New Jersey Zinc Co., which has been mining this class of ore and carrying big equipment, seems to have lost prestige and shipments are comparatively light from the mines of this company. Such iron pyrite as was marketed during the month came from the electro-static separating plant of the Zinc Concentrating Co., of Cuba City, all sold to the General Chemical Co. The Grasselli Chemical Co., which for many years offered a fair outlet for this class of ore, has withdrawn from the local market entirely. Thousands of tons of pyritic concentrate is held in the field for which apparently no market exists. At one time from 20,000 to 30,000 tons of pyrite was marketed annually in this field.

The foreign miner is not popular in this region, and is being replaced in considerable number with blacks from the south. Where tractable and inclined to refrain from agitation the foreign miner is permitted to go along. Negro miners are making good; in fact five shovelers at the Graham mine have a record of 35 to 40 tons, of mine head, on each 9-hour shift and have earned as high as \$12 per day. Employers state that the black miner is American at heart and without liquor develops into a good workman quickly.

Deliveries of zinc ore and lead ore, from mines to sepa-

rating-plants in this district, and from mines to smelters direct, were made by districts for May as shown here:

District	Zinc, lb	Lead, lb
Benton	6,168,000	422,000
Galena	3,254,000	160,000
Livingston	2,222,000	80,000
Cuba City	2,184,000	210,000
Highland	1,020,000	160,000
Hazel Green	724,000
Day Siding	422,000	160,000
Millbrig	390,000	82,000
Linden	314,000
Shullsburg	276,000
Total	16,974,000	1,274,000

Deliveries of high-grade blende from electro-magnetic separating plants to smelters, were made for May by the following companies:

Company	Lb.
Mineral Point Zinc Co.....	4,042,000
Wisconsin Zinc Roasters	2,894,000
Zinc Concentrating Co.....	610,000
National Ore Separators	532,000
Total	8,078,000

BRITISH COLUMBIA

ALASKAN-CANADIAN BOUNDARY TO BE RE-MARKED.

STEWART.—The Patricia, Magee, and Montana groups of mineral claims, situated on the Marmot river, are to be developed during the summer. On the Patricia a four-foot vein of good ore has been opened, samples from which have given returns from \$15 to \$35 in gold, and as high as \$62 in silver.

J. D. Craig, an engineer for the Dominion government, has taken charge of the Canadian party, whose duty it will be to co-operate with United States surveyors in the establishment of a clearer definition of the Canadian-Alaskan boundary. Stone cairns on the mountains, bronze monuments, and a 20-ft. lane through the forest will mark the boundary by the time the engineers have finished their season's work. Commenting on his task Mr. Craig said: "The wisdom of marking the boundary some sixteen years ago—a marking which has since become more or less obliterated—is now apparent. As it happens about 90% of the silver recently discovered has been on the Canadian side. If the survey had been delayed it might have made the settlement of the line more difficult to agree upon." A neutral strip of 60 ft. on either side of the boundary is to be reserved, as is the custom on the whole 5000 miles of Alaskan and U. S. boundary, except where titles to the strip had previously passed out of the hands of the Government. Mr. Craig does not think this will mean that the strip will be withheld from mineral development, but that in the case of the location of mineral special leases will have to be obtained from Ottawa or Washington.

ALICE ARM.—The snow is rapidly disappearing in this district and mining is becoming active. The Dolly Varden mine again is in full operation and ore shipments are being received at tide-water. The La Rose property is to be developed further and a force of men has been

put to work. The Moose prospect also is to be opened up and the McLennan Silver Mines Ltd. already has started work on the Royal group adjoining the Dolly Varden. In the course of the last few weeks a great many miners and prospectors have arrived and as the snow recedes prospectors and miners will make their way up both the Kutsault and the Illiance rivers.

KAMLOOPS. It begins to look as though the Stump Lake mine of the Donohoe Mines Corporation is to produce within a short time. Machinery has been ordered for a modern concentrating plant, the foundations for which are now being constructed. The plant, it is hoped, will be ready for operation in three or four months at the outside. It will have a capacity of 50 tons per day. The ore of the Donohoe mine is principally silver bearing but contains besides gold, lead, and copper, the metal content varying in value from \$20 to \$600. The prop-

SIDE-DUMP ORE-CARS AT BRITANNIA MINE, B. C.

erty recently was inspected by William J. Shedwick, Jr., of the Kennecott Copper Corporation, and Lewis A. Levensaler and Francis N. Myers, all of whom are mining engineers.

NELSON.—The Nelson Mining & Development Co., which is interested in a number of properties in the Lardeau and Sandon district, is preparing for development work. The Whitewater and Comstock groups on Cascade creek, Lardeau, are to be opened, and, to facilitate this, the construction of a nine-mile wagon-road is planned. On the Comstock leases there is a good mill-site, and the erection of a mill is being considered. Some good silver-lead veins have been uncovered on the Zineton property near Sandon and, in addition to high-grade ore, a considerable quantity of good milling ore has been exposed. Clarence A. Marsh, secretary of the company, also is interested in the Gold Cure mine, situated on the South Fork of Kaslo, and it is his intention to start development here immediately. Ore rich in silver and lead already is in evidence and if the results of further work are satisfactory the idea is to build a concentration and flotation plant having an initial capacity of 50 tons per day.

TRAIL, B. C.—Receipts at the Trail smelter of the Consolidated Mining & Smelting Company of Canada for the week ended May 31 were 6832 tons, of which 67

was concentrate. One of the noteworthy independent shippers was the Bluebell, of Riondell, which contributed 180 tons, thus indicating that this mine, for a time inactive because of lack of water-power, has resumed operation. Other shippers, apart from the company's properties, were Electric Point, Boundary, Washington, 196 tons; Florence, Princess Creek, 67 tons; Josie, Rossland, 170 tons; North Star, Kimberley, 181 tons; No. 1 mine, Ainsworth, 127 tons; and the Tam O'Shanter, Riondell, 56 tons. The Sullivan mine, Kimberley, evidently is getting back to normal, having shipped 5367 tons of zinc ore and 296 tons of lead ore during the week. The total amount of ore to be received at the smelter up to the present year is 110,298 tons.

VICTORIA.—According to report, Alder island, one of the smaller of the Queen Charlotte group, consists of one large deposit of metallic arsenic. The two or three claims staked cover the entire island and samples taken indiscriminately give returns running from 18% to 24% arsenic, while the locator states that it is possible to obtain specimens of almost pure mineral. This is interesting because it appears to be the first such deposit of which there is record in British Columbia, although for years arsenic has been produced as a by-product from the arseno-pyrite ores of the Hedley Gold Mining Company.

ONTARIO

REPORT OF DOME MINES, LTD.

TORONTO.—At the annual meeting of the Mining Corporation of Canada on June 5 it was announced that the company is associated with W. B. Thompson & Co., of New York, in the option on the Flin Flon copper mine in North-Western Manitoba. The property is being explored by the sinking of shafts and drifting on the vein, with a view to confirming the results of diamond-drilling, which indicated 20,000,000 to 30,000,000 tons of copper ore. The option runs until next March, but development work may justify decisive action before that time. The amount of capital required to establish the enterprise is estimated at from \$8,000,000 to \$10,000,000. The shareholders were informed that although the corporation has done much exploration in various parts of the world, it is now intended to confine its operations largely to this continent.

PORCUPINE.—In addition to increasing the minimum wage-rate the leading companies have classified their labor, giving a premium to skilled workers. These changes have done much to stabilize the labor situation and allay unrest and the tendency to wander from camp to camp.

The annual report of the Dome Mines for the year ended March 31 shows the total production to be \$1,773,374; operation and maintenance expenses were \$930,762, leaving net earnings of \$842,612, which, with revenue from other sources amounting to \$109,372, gives a total net profit of \$951,984. Deductions amounting to \$600,170 were made, chiefly for depletion of properties, depreciation, and replacement, leaving a net surplus for

the year of \$351,814. This is regarded as a highly favorable showing in view of the fact that the mill was only in operation for 10½ months and that production was considerably curtailed by labor shortage. The total quantity of ore treated was 270,080 tons, the average yield being \$6.506 per ton, the recovery being 94.295%. Regarding ore-reserves the report is somewhat conservative, avoiding any specific statement, but intimating that the reserves are sufficient to enable the plant to continue operating to capacity for three or four years. As regards development work on the Dome Extension reference is made to various ore-bodies found with the ore valued at from \$4.45 to \$4.95 per ton.

KIRKLAND LAKE.—During April the Lake Shore produced bullion to the amount of \$35,388 from the treatment of 1860 tons of ore, mill-heads, being below the former average, amounting to \$19.50 per ton. At the Bidgood the vein, which was 8 ft. wide on the surface, has widened to 15 ft. at the 100-ft. level. The shaft is down 140 ft. The Moffat-Hall Gold Mines, which owns a group of claims near the Bidgood, has erected buildings and has a force engaged in stripping and trenching work.

COBALT.—Announcement is made that the Bailey Silver Mines will send out its first shipment of ore soon, and that sufficient ore is in sight to assure regular shipments for some time, 23,000 tons of fairly high-grade ore being already blocked out. Several veins only await development to bring them to a point of productivity. It is over five years since the Bailey was worked, curtailment having been caused by litigation that began in 1915 and only ended this year.

The return of foreign-born laborers to their former homes in Middle and Eastern Europe appears to have about run its course, and has left a steadier class of workmen at the mines. It has increased the percentage of British and American born citizens in all the leading mining camps of Northern Ontario. That new immigrants from the British Isles are destined to further add to this favorable situation is indicated in a statement by a leading mine manager that he noted an encouraging sprinkling of these new recruits to the ranks of Canadian labor. A further favorable sign is statistics from official records which show an increasing number of applications from former citizens of various European countries, who are now seeking Canadian naturalization.

At the Peterson Lake, a shipment of high-grade ore is being assembled, and is estimated to contain about 50,000 oz. of silver. The re-treatment of sand tailing by contract in the mill of the Dominion Reduction Co. will not commence before the end of July. At the annual meeting, the following directors were elected: W. A. Lamport, president; J. E. Carter, vice-president; and E. Bareham, W. H. G. Browne, A. G. Cumming, D. E. Kennedy, C. A. McLean, A. H. B. Moore, C. M. Nickel, and P. M. Goff, directors. The Crown Reserve Mining Co. has acquired an option on the Hylands-Offor group of claims, situated in the township of Whitney in the Porcupine district. It is proposed to explore the property by using diamond-drills.

OPENING FOR GOVERNMENT METALLURGIST

A vacancy in the Bureau of Mines for services in the field, at \$2600 to \$4000 a year, is announced. The duties of the appointee will be to conduct investigations at one of the mining experiment stations authorized by the act of Congress of March 3, 1915, and established July 1, 1916; to supervise investigation and to disseminate information with a view to improving conditions in the mining, quarrying, metallurgical, and other mineral industries in the district served by the station, especially with a view to preventing unnecessary waste of resources and otherwise contributing to the advancement of these industries. Applicants must have graduated in mining engineering or metallurgy from a college or university of recognized standing and have had at least five years of responsible experience. In such work, of which at least two years must have been along metallurgical lines. Applicants must not have reached their fiftieth birthday on the date of the examination. Age limits do not apply to persons entitled to preference because of military or naval service. Applicants should at once apply for Form 2118, stating the title of the examination desired, to the Civil Service Commission, Washington, D. C.; the Secretary of the United States Civil Service Board, Customhouse, Boston, Mass.; New York, N. Y.; New Orleans, La.; Honolulu, Hawaii; Post Office, Philadelphia, Pa.; Atlanta, Ga.; Cincinnati, Ohio; Chicago, Ill.; St. Paul, Minn.; Seattle, Wash.; San Francisco, Cal.; Old Customhouse, St. Louis, Mo.; Administration Building, Balboa Heights, Canal Zone; or to the Chairman of the Porto Rican Civil Service Commission, San Juan, P. R.

ARIZONA

Prescott.—The New Cornelia Copper Co. recently fired one of its huge blasts. The company late last year completed the lay-out of powder chambers and connecting tunnels in its hill No. 3, the length of underground excavations being 661 ft. This was loaded with 80,000 lb. of Trojan nitro-starch powder and fired by an electric current of 110 volts. The cost of the blast for labor and supplies was \$15,305, which with the cost of drifting and excavating made a total of \$17,720. Approximately 300,000 tons of ore was loosened by the blast, the cost averaging about 6c. per ton.

MISSOURI

Joplin.—Hand-jigs have returned to the Oklahoma-Kansas mining district. Scores of these primitive machines are being used about the field to a great advantage, especially in developing properties to the point where it is known definitely that they will justify the expenditure of money for a concentrating plant. Some of the best mines in the district have been developed by the hand-jig. Among them are the Montreal, the Empire, the LaSalle, and the Douthat. The Coalgate was originally operated with hand-jigs, then steam-jigs were built in the open and operated for a while before a building was erected over them; then it was thought best to convert the cheap plant into a better one, which is now being done. Among those which are being operated now are the McConnell, the Powers, and the Barker-Howell, south of Baxter; the Sedalia, south of Hockerville; the High Grade at Quapaw; and the Reserve, west of Hockerville.

A large number of mines near Aurora continue at work and others will resume operations after repairs are made to machinery and the water is pumped from the mines.—**Hunter & Co.** have completed the cleaning up of the ore taken from the Decker-McCrellas Co. mine, which was treated at the Louisville mill, and will stop milling work until a new shaft is sunk. Two cars of high-grade silicate were sold last week.—**Cutright & Co.** have been pumping water and have lowered it to 75 ft. When they get down to 87 ft. they will be able to work in the drift. The mill machinery will be in shape to start in about 10 days and it is the intention to start mining then.—**Mill & Co.** are awaiting the arrival of repairs for their engine, which was broken recently, to resume operations at the mill. They have taken out a quantity of rich silicate while waiting for the engine repairs.

Miners will soon be leaving in large numbers for the harvest fields. Mining companies will then be competing with one another for the scant labor supply. It will be a most opportune time to shut-down. A plan suggested by one operator is to shut-down all mines during the wheat harvest and over the Fourth of July, say from June 15 to July 15. This, he says, would get rid of the surplus stocks of ore and restore a fair market price.

A large cave, lined with great chunks of almost pure lead and zinc, extending more than 100 ft. in length and about 30 ft. in width, has been discovered in the Red Skin mine. A large slab on a roof of a drift was shot down, and Fred Bouldin, manager of the mine, noticed an opening. He obtained a ladder, climbed up, and found the big chamber. He took to Miami several specimens of ore taken from the cave and said that it was filled to a depth of several feet on all sides with almost pure lead and zinc.

OREGON

Holland.—The old Cowen quartz mine near here has been acquired by A. C. Stewart and associates. It is reported that the new owners will erect a modern reduction plant on the property. The Cowen mine was located in 1880 and was worked in a crude way, the ore being hauled ten miles to an arrastra. Considerable lower-grade ore is still available.

Medford.—The Bolen Creek Mining Co. has filed an application with the State Engineer for a water-right on Sucker creek sufficient to develop 90 hp. for operating its mine equipment in the Waldo district.—**The War Eagle Mining Co.**, in the Gold Hill district, has a crew doing further development on its mercury deposits. The company is operating two 12-pipe mercury-furnaces on ore averaging 17% and better. It proposes to add a 25-ton furnace this season.

WASHINGTON

Stevens County.—The Silver Trail company reports a large body of silver-lead ore on the 700-ft. level in the Bonanza mine. A contract for hauling to the Northport smelter will be let soon.—**The new compressor** arrived at the Aichan Bee mine several days ago and will be put in operation at once. The tunnel is in 462 ft. It has gone through 12 ft. of blue lime and has now broken through the iron crust that usually has been found over good veins.

WARREN G. HARDING

Warren G. Harding, who has been nominated as candidate for President by the Republican convention, has always been a resident of Ohio, which State he has represented as United States Senator since 1914. In private business life he is publisher of the "Marion Star". He was born on a farm near the village of Bloomington Grove, Morrow county, Ohio, November 2, 1865, the eldest of eight children. His father, George T. Harding, was a country doctor, whose forebears came from Scotland. Before going to Ohio the Hardings were residents of Pennsylvania, where some of them were massacred by Indians. Others fought in the Revolutionary war. The mother of Warren, Phoebe Dickerson Harding, was descended from an old-time Holland-Dutch family, the Van Kirks. In his youth Warren Harding lived the life of a farmer boy, attending the village school until 14 years of age, when he entered Ohio Central College at Iberia, from which he was graduated. As editor of the college paper he first displayed talent for journalism. He was obliged to stop school now and then and earn the money with which to pursue his college course. At one time he cut corn, at another painted barns, and at still another drove a team and helped to grade the roadbed of a new railway. At 17 he taught a district school and played a horn in the village brass-band. At odd times he worked in the village printing-office, in time becoming an expert typesetter, and later a linotype operator. He is a practical pressman and a job-printer, and as a 'make-up man' is said to have few equals. The luck piece he has carried as a Senator is the old printer's rule he used when he was sticking type.

In 1884 Dr. Harding moved his family to Marion. A short time afterward the father purchased for Warren Harding the "Star", then a small paper. On the paper Warren Harding performed every function from 'devil' to managing editor. In all the years the Senator has owned it there has never been a strike or a threatened one. Senator Harding is closely identified with many other large business enterprises in Marion and other parts of the State. He is director of a bank and several large manufacturing plants, and is a trustee of the Trinity Baptist Church. Harding has twice represented the thirteenth senatorial district of Ohio in the State Legislature and served one term as Lieutenant-Governor. At the 1914 election, Mr. Harding was elected United States Senator by a majority of more than 100,000, running 73,000 ahead of the next highest on the ticket. In the Senate he is a member of the Committee on Foreign Relations. Senator Harding married Miss Florence Kling in 1891.

FLOTATION LITIGATION

The flotation litigation, involving a number of copper companies and the Butte & Superior Mining Co., promises to be a long drawn out affair. A new step taken by the Miami Copper Co. against the Minerals Separation company will probably delay materially the litigation between those two companies. Minerals Separation had brought contempt proceedings against Miami for alleged continued infringement of patents in defiance of injunction. Miami countered with a request that the original suit be re-opened on the grounds of alleged new evidence. The United States Circuit Court of Appeals at Philadelphia in determining this request will have to decide whether the so-called new evidence would have received favorable consideration had it been presented at the time of the original trial. Hearing on the contempt proceedings has been set for June 15 at Philadelphia. Pending these hearings the work of taking an accounting of Miami's operations during the past few years has been suspended. In the meantime hearings set for preliminary steps in the Nevada Consolidated and Magma cases at Portland have been postponed until mid-July.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Gerald H. Hatton is at Dayton, Nevada.

A. J. Evelyn is leaving Mexico for Boston.

C. S. Waite has moved to Reno from San Francisco.

A. G. McGregor, of Warren, Arizona, is in New York.

V. H. Wilhelm, recently in Mexico, is now at Stewart, B. C.

P. L. Chase, of Denver, is examining mines at Lake City, Colorado.

G. S. Eldridge, of Vancouver, B. C., was in San Francisco this week.

E. F. Davis, of Salt Lake City, has moved to Albuquerque, New Mexico.

F. H. Probert is delivering a series of lectures on mining at Yale university.

C. F. Sturtevant has returned from South America and is now at Salt Lake City.

D. J. Richards has returned from Kennecott, Alaska, to Buena Vista, Colorado.

Grenville A. Collins has resumed consulting mining practice at 2006 L. C. Smith Bdg., Seattle.

J. C. Pickering has opened an office as consulting mining engineer at Avenida Juarez No. 83, Mexico City.

Roscoe Edlycan, of Denver, Colorado, is now at the Wilshire Bishop Creek mine, near Bishop, California.

Samuel W. Cohen of Montreal has recently purchased the Poulin asbestos mine at East Broughton, Montreal.

Alfred Hurst has been appointed superintendent for the Angels Camp Deep Mining Co., at Angels, California.

Alfred James, who has been on a visit to Mexico, was at Laredo on June 16 and, it is hoped, will visit San Francisco.

Errol MacBoyle, president of the Durango Silver Mines Co., has left San Francisco to inspect the company's properties in Mexico.

G. H. Clevenger, consulting metallurgist to the U. S. Smelting, Refining & Mining Co., is on his way back to Boston from California.

James S. Wroth, of New York, has sailed for South America, where he will be engaged on professional business for about a year in Peru, Chile, and Bolivia.

James O. Greenan has gone to Berkeley, California, where he expects to be for some time. Following his resignation as superintendent of the Fagan Con. Silver mine, at Simon, Nevada, E. W. King was appointed his successor.

R. G. McConnell, for many years deputy minister of the Canadian Department of Mines, has been superannuated at his own request, and Charles Camsell, superintendent of the British Columbia branch office of the Geological Survey since its establishment, two years ago, has been appointed in his place.

James F. Parks, superintendent for the Plymouth Consolidated Gold Mines in Amador county, California, and one of the most esteemed mining men in California, died on Wednesday, June 9, at the age of 38 years, in the Sisters Hospital at Sacramento, following an operation for appendicitis. Interment took place on Friday at Plymouth. He was the son of the late James F. Parks, formerly superintendent for the Kennedy Mining Co., and was a brother of Mrs. F. W. Bradley and Mrs. John F. Davis. The Parks family has been associated with the history of the Mother Lode in Amador county since its discovery. Not only the Plymouth Consolidated Gold Mines, but the mining community of California suffers a loss. Deep regret will be felt that a man so capable and honorable should have been taken while in the prime of manhood and effectiveness.

THE METAL MARKET

METAL PRICES

San Francisco, June 15

Aluminum dust, cents per pound.....	65
Antimony, cents per pound.....	19
Copper, electrolytic, cents per pound.....	10

EASTERN METAL MARKET

(By wire from New York)

June 14—Copper is inactive and firm. Lead is quiet and steady. Zinc is dull but steady.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2, on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46 1/2 pence per ounce (1025 fine) calculated at the normal rate of exchange.

THE BANKING CONSORTIUM FOR CHINA

Thomas W. Lamont of J. P. Morgan & Co. is quoted as follows: "In October 1918, the United States proposed to Great Britain, France, and Japan that they support banking groups in forming of a new consortium for assisting China in the development of public enterprises. The United States proposed that the new consortium have a wider scope than the old one, that it be a free and full partnership, and that operations or concessions on which substantial progress had not been made should be pooled with the consortium whose operations would prevent future setting up of special spheres of influence. The United States had stress on this latter point as done away with international jealousies and helping preserve the integrity of China.

It was not to be the aim of the consortium to concern itself with general enterprises, but rather only basic enterprises such as development of transportation, highways, currency, etc., that would establish a sounder economic condition. Its operations should deal primarily with loans to the Chinese republic or its provinces. These proposals were approved by the other governments, and the banking groups formed directed their representatives to meet for organization in Paris in May, 1919. These represented a much larger banking group than in the old consortium. The American banking group had been expanded from the former 5 to 31 member banks.

"The governments of Great Britain, France, and United States approved without change the agreement reached, but Japan qualified its approval by reserving portions of Manchuria and Mongolia from the scope of the consortium. I was requested by American group and the state department to visit Japan and China and report on the whole situation. In Japan I ascertained that misapprehension existed as to the objects of the consortium; but after conferences I found the Japanese bankers unanimous in the desire to enter the consortium without reservation, and they expected formal approval from their government. If Japan should continue to withhold its assent, it would be the chief loser by its failure to become a member.

"In China I have had important discussions with bankers and men of affairs, and can lay down certain principles which the American group will advocate and the consortium will follow. It will undertake operations only when the people of China desire. If China desires its assistance, it will be for China to render cordial co-operation. We have to see that any loans are for constructive and not wasteful purposes, and some proper system of audit must be mutually worked out to make certain the proper application of funds. Such audit plan does not interfere with China's right to govern her own affairs.

"The consortium's second responsibility is to its investors at home to see that their investments are designed and expended for constructive purposes. The American group—and I am sure the other banking groups—have strong faith in the resources, industry, and integrity of the Chinese people. They believe there exists in China a large amount of wealth, liquid as well as latent, which it is their confident belief needs only to be mobilized.

MONEY AND EXCHANGE

Foreign quotations on June 15 are as follows:

Currency	1918	1919	1920
Sterling, dollars: Cable	3.24 1/2		
" Demand	3.25 1/2		
Francs, cents: Cable	7.78		
" Demand	7.80		
Lira, cents: Cable	7.71		
" Demand	7.75		

Eastern Metal Market

New York, June 9.

Demand for all the metals is still light and the effect of the railroad demoralization are still apparent.

The copper market is inactive but prices are fairly steady. Quietness pervades the tin market and prices have fallen sharply.

Buying of lead is not heavy but prices are firm.

The zinc market is a little stronger and prices fairly active.

Antimony demand is light and prices lower.

IRON AND STEEL

Producers and industrial consumers of steel are still so involved in delivery troubles that new buying and developments affecting prices are entirely secondary, says "The Iron Age". In some published statements the week's movement of iron and steel has been put too favorably. Chicago has made practically no gain; concerning Pittsburgh conditions, reports are conflicting. However, the strike is wearing out, and in some districts more rapid improvement is promised for the coming fortnight.

The fuel situation still hampers some pig-iron steel producers seriously. Foundries in all parts of the country are crippled for lack of coke, and in turn lack of castings is cutting down operations of machine-shops and automobile factories. The decrease in automobile production is due in part, however, to a slump in demand for all but the cheaper cars. Men laid off by automobile makers at Detroit have appeared in the Chicago district seeking work at steel-plants.

Inquiry for pig-iron for export, including both foundry and steel-making grades, is active and it would be possible to export considerable if the iron could be obtained, but furnaces at the present low production are slow to take foreign business.

COPPER

There is very little change in the general situation. Demand continues very light and production is curtailed because of labor and railroad difficulties. It is stated that in the case of copper, lead, and some of the metals the only way to make shipments is in train loads made up by various producers. There has been a slight easing in prices, that is, leading producers will sell electrolytic and Lake copper at 19c., New York, for June and July delivery instead of June only. For forward delivery a slight premium is asked. There is constantly a fair demand for export. Confidence is expressed that the future of copper is bright and that ultimately prices will be higher because of a large inevitable demand.

TIN

The feature of the week has been the decline of spot Straits to new low levels, 48.50c., New York, having been the bottom on June 7. The week has been a quiet one with only one active day; on Friday, June 4, about 325 tons of Straits tin was sold on the New York Metal Exchange, mostly future shipment, at prices ranging from 48.50c. to 48.75c. For metal spot on dock, 49c. was realized. On June 1, 2, and 3 sales were small at prices ranging from 49.62½c. to 50.62½c. for future shipment. There has been a good inquiry thus far this week. Yesterday spot Straits was higher than on Monday at 39.25c., New York, due to an advance in London of £4 per ton to £280 yesterday over Monday. The London quotation a week ago was £287 5s. per ton. Arrivals thus far this month have been 1185 tons, with the quantity afloat reported at 5045 tons.

LEAD

This market presents such a mixed aspect that quotations

for early delivery are anybody's guess. Very little business is being done, though the tone of the market remains firm. The steadiness is due to short supplies, the scarcity in general being pronounced, without doubt. Another cause of the firmness is the fact that there are few sellers. Because of this lack of offerings and of buying, quotations are largely nominal at 8.80c. to 9c., New York, for early or June delivery, with St. Louis quoted at 8.50c. to 8.65c. The leading interest's prices are unchanged at 8.25c., St. Louis, or 8.50c., New York. Spot lead is held firm at 9c. to 9.37½c., New York, with sales made yesterday at 9c. The fact that foreign lead or lead re-shipped from England can be sold in New York at a profit at 9c. is not taken seriously, as the margin of profit is too small.

ZINC

This market has undergone very little change, except possibly a slight improvement in tone. Demand is still hand to mouth. The London market has been stronger and so has sterling exchange the last day or two, which largely explains the firmness. Another factor is the slackening in production due to strikes, labor, and fuel troubles at smelting centres. Prime Western for delivery in the next three months is quoted at 7.75c., St. Louis, or 8.10c., New York. Large producers continue to meet the demand of their regular consumers but otherwise are not actively interested.

ANTIMONY

There is little demand and prices are lower at 8.75c., New York, duty paid, for the better grades and 8.62½c. for the poorer for wholesale lots for early delivery.

ALUMINUM

Virgin metal, 98 to 99% pure, is quoted at 33c. per pound, New York, for wholesale lots for early delivery by the leading producer, with other interests asking 31.50c., New York.

ORES

Tungsten: The tariff matter is now postponed until next winter when Congress meets again and the market is left to its own course until that time at least. A resumption of buying is expected now. In the meantime prices are nominal at \$6.50 to \$7 per unit for Chinese ore, which is the chief source of supply at present.

Ferro-tungsten is quiet at 85c. to \$1.15 per pound of contained tungsten.

Molybdenum: The market is dead and prices are nominal at 75c. per pound of MoS₂ in regular concentrate.

Manganese: Little business is reported, although demand is strong and good offerings could easily be disposed of at 80c. to \$1 per unit for high-grade ore. Imports in April were 35,088 tons, bringing the total for the 10 months ended April 30, 1920, to 186,986 tons, as compared with 421,258 for the same 10 months in 1919.

Manganese-Iron Alloy: There has been no changes or developments. Prices are the same as a week ago at \$250 for June and \$200, delivered, for last half for domestic ferro-manganese. Sales have been light as well as demand. Imports in April were 3018 tons, which is only slightly above the monthly average for the first quarter of this year and for all of 1919. Spiegeleisen is quiet but strong at \$75, furnace.

During the last year production of copper has been at the rate of about 140,000,000 lb. of refined metal per month. Recently, however, even this curtailed production has not been sold. The president of one of the larger copper companies estimates surplus stocks of refined copper on hand at 650,000,000 pounds.

T. A. RICKARD. . . . Editor

AS many of our readers are aware, the editor of this paper has written a small book on 'Technical Writing' recently published by John Wiley & Sons, New York. He takes advantage of the opportunity to invite criticisms and will be grateful to those who will take the trouble to draw his attention to errors of any kind that they may detect in the course of their reading of the book.

HOARDING of silver and gold in the countries of the Orient causes a large proportion of the world's annual output of the precious metals to be withdrawn from use in commerce. It is stated, for example, that the Military Governor of the Province of Shahnsi, in China, has issued a proclamation with a view to persuading the wealthy people of Taiyuanfu and other cities in Shahnsi not to hoard silver in their gardens and fields, but to show confidence in their officials by using the metal for trading purposes. It is estimated that the natives of this Chinese province have hidden silver 'shoes' by the thousand, as well as silver dollars, in their cellars underground. In view of the absence of strong banks and the lack of confidence in the Government, it is doubtful whether the Governor's proclamation will cause the natives to 'dig up' their silver.

ORE-BUYERS and mine-operators in the Miami district of Oklahoma are both quite certain that they are not liable for the payment of county taxes on several thousand tons of lead and zinc concentrates that had accumulated in the bins of the mining companies on January 1, as a result of the shortage of railroad cars. Mr. E. E. Shipley, the local tax-collector, is not particular as to who pays the taxes, but he is persistently and consistently insistent that somebody must pay them. The mining men aver that they had sold the concentrates and should not be taxed for material they did not own, just because it happened to be stored on their premises. The ore-purchasers as firmly maintain that until delivery had been effected the concentrates were not their property and should not be assessed to them. We hope the miners will make good their contention.

MEXICO'S trade with the United States is increasing steadily. In 1910, says the National City Bank of New York, it was \$115,000,000; the revolutions of Madero and Huerta reduced it to \$110,000,000 in 1915; since then, despite the Villa and Carranza revolutions, it has

risen steadily from \$191,000,000 in 1917, to \$245,000,000 in 1918, and \$278,000,000 in 1919. According to the latest figures, this international trade will be at least \$300,000,000 for the fiscal year ending on June 30. Of the total commerce last year, \$148,926,000 represented our imports from Mexico and \$131,452,000 our exports to that country. Among our imports the chief products are sisal (a vegetal fibre, like hemp), petroleum, copper, cotton, coffee, hides, and lead.

RECENT episodes in California have shown that the disciplining of wild-cat mining schemes by the Commissioner of Corporations is hardly sufficient, under the existing law, to prevent fraud. Clever promoters of an irresponsible character are able to circumvent the statute. We note that the West Australian parliament has passed an act recently for the purpose "of protecting the public from the operations of wild-cat schemes. The regulation assures that all money subscribed for developing mines shall be used." We hope it will. The cynic will laugh at this belated spasm of virtue at Perth, for it comes at a date when the gold-mining industry of Western Australia has passed, in large measure, out of the exuberant stage and is marked by the sobriety of proximate exhaustion. Time was when the 'wild-cats' of Kalgoorlie and Coolgardie were so ferocious, it is said, that they accounted for the lack of rabbits in Western Australia.

"MR. NELSON BIGELOW, of Silver Centre, was admitted to the Providence Hospital at Haileybury yesterday suffering from an accident to his face and hands, caused by the exploding of some dynamite. According to Mr. Bigelow's own story, he was working at a mine, and blasting at intervals. One blast failed to go off and he endeavored to explode the charge by hitting the cap with a hammer. The force of the explosion hurled him some 30 ft., badly cutting his hands and left portion of his face. Assistance was rendered him by some of the men, and he was rushed to the hospital here. His injuries are not considered to be dangerously serious and a speedy recovery is looked for." This dispatch is from an entirely reliable source in Ontario. We have heard of the man who insisted on crimping caps with his teeth, and did it once too often, and we have distinct recollections of the man who drilled into the socket of a missed hole to save a few inches of drilling; but we believe that the performance of this gentleman is unique.

Fate has been unkind to the undertakers of Silver Centre. Such folly as caused the accident might have led to the loss of many more valuable lives. Has all the "Safety First" propaganda been used by Mr. Bigelow for lighting his pipe?

CHANGES in the provisions of the Yukon Placer Mining Act are being considered by the Canadian parliament. In the hope of stimulating placer mining it is proposed to lease the land lying along the favorably situated creeks for a rental of \$25 per mile. The original lease of one year may be renewed twice for a similar period provided \$1000 is expended in prospecting and development. In respect of ground that has been once worked and abandoned, the maximum distance allowed in a single lease is to be five miles, and within it as many claims of standard size as desired subsequently may be staked. The lease in virgin territory must not exceed one mile along the creek, and only one claim can be staked; it may, however, have the dimensions of a discovery claim, which is three times the regulation size. Large areas of gold-bearing gravel that cannot be profitably worked by the methods of the individual miner are sufficiently rich to be exploited on a big scale by means of more elaborate machinery and equipment. To warrant the investment of the necessary capital there must be assurance of a more extended scope of operation and to this end the proposed modifications in the law were suggested by the Yukon Development League. If the Act be passed, as seems likely, the region made famous by the Klondike may again contribute to the world's dwindling production of gold.

PSEUDOMORPHS of geology are common on the oil fields; the science of Lyell and Le Conte is given a Koster & Biall treatment that is the essence of caricature. We have been favored with the copy of a report on an oil venture in Robertson county, Texas. In that report we are told that "the first horizon stone is principally of sand; however, some lime contamination was in evidence. Iron silicate of considerable salacious properties was in evidence." Some kinds of burlesque are salacious. "The erosions that have come from these domes show a small trace of carbon and also slight sulphur contamination." They ought to; in truth, the language needs to be fumigated. The writer is modest withal; he says: "I do not insure the finding of oil and gas, but when one puts their best efforts forward in a diligent search and finds such great nucleus of evidence, it is reasonable to expect that those who may drill upon the advice of a geologist are likely to be rewarded by the finding of the commercial fluids." Blessed are they that expect much, for they shall be comforted with the thought that they might have lost their money in some other way. "The epochs that lay at their respective levels according to all geological research, show this zone to be properly laid down and all affinities are in keeping with things that we look for, hence where so much evidence has concentrated in one locality and nothing being found radically contrary, it is quite likely that our diag-

nosis will prove correct." But like other diagnoses by the ignorant, it is more likely to prove fallacious. We wonder how he pronounces "research". The reference to "affinities" is dangerous; should one call this a geologic *crime passionel*?

HENCEFORTH the Canadian Mining Institute will be known as the Canadian Institute of Mining and Metallurgy. The change follows in the wake of the example set by the American Institute of Mining Engineers, which is now the American Institute of Mining and Metallurgical Engineers. These North American professional organizations have copied the style of the Mining and Metallurgical Society of America and the older British society, the Institution of Mining and Metallurgy. We regret the attempt to be specific, whereby the names of these societies become exclusive of many engineers engaged in the mining industry and therefore properly members of such organizations. The geologist and the chemist, for example, are apparently excluded by the effort to include the metallurgist and his art in the title. However, it seems to be the fashion to add to the length of these names without adding to their descriptive value, so the less said the better; but it is worth while to record the changes as they are put into effect. Whatever its name, we wish continued success to the Canadian Institute. We regret to note that Mr. H. Mortimer-Lamb has found it necessary to retire, with the honor of appointment as Secretary Emeritus. Upon its secretary a technical society depends largely for its success. We hope the Canadian Institute will find a good one to replace Mr. Mortimer-Lamb, but it will be difficult to do so.

STATISTICS of immigration and emigration in 1919 show that the net gain to our population last year was only 4636, as compared with a net gain of 1,017,957 in 1913, which was the record year in this respect. The alien outflow in 1919 was the largest for five years; the departures were mostly to Italy, a fact that has led many to place the responsibility on prohibition. We doubt whether the 18th Amendment was the cause, except in minor degree. However, it is noteworthy that there was a heavy emigration from this country to the shores of the Mediterranean, whereas, on the other hand, there was a notable increase of immigration from the British isles and from France; so that there seemed to be a satisfactory reversal of the flow that was bringing us an excessive proportion of the poorer (in character and intelligence, which are more important than wealth) peoples of south-eastern Europe. The departures numbered 392,526, as against 397,162 arrivals; and it is remarkable that the number of aliens entering the United States from the Canadian and Mexican borders was the largest since 1914. At the present time the influx at the port of New York is about 10,000 per week, so that the current year ought to show a considerable change in the statistical record. As yet the entry of aliens into the United States is still subject to restrictions established during the War; none can enter except under passport

issued by our representative at the port of embarkation after the applicant has undergone examination, and the steamship companies are subject to punishment under the law if they admit any alien excluded by existing regulations. The legal conclusion of the War, by ratification of peace, should facilitate immigration considerably, but we hope that the proper restrictions and regulations will not be waived even then, for reasons that we discuss in another column.

Geology for Miners

In this issue we print the third of a series of articles on the ore deposits of Mexico by Mr. S. J. Lewis. The two previous ones appeared in our issues of March 20 and March 27, the continuity of publication having been broken by interruption in the postal service. In his latest contribution to the study of the subject, Mr. Lewis describes and analyzes the distribution of ores in sedimentary rocks, more particularly those not at the contact with igneous intrusions. He instances El Oro, where rich veins of gold-silver ore have been followed through shale into andesite and again into shale. Although the ore does not follow the contacts between the shale and the intruding andesite, yet it is evident that the formation of the vein-fractures and their enrichment by the precipitation of valuable minerals has come in the wake of the structural conditions created by the bending and breaking of the shale near a mass of hot rock within the horizon of solutions containing the precious metals. Between Sultepec and Zacualpan somewhat similar conditions obtain. At Ajuchitlan the distribution of the ore is more immediately associated with a contact, where a tongue of porphyry has broken into, and shattered, the shale. This reminds us of the excellent work done by Mr. Louis E. Reber at Jerome, Arizona, and of his remark: "Important ore deposits are usually related to apophyses or outlying porphyritic phases of batholithic intrusions rather than along the walls of the main masses." We shall not review Mr. Lewis's article in further detail, as we desire at this time merely to point out that he is giving the miner the information most needed in his search for ore underground. The analysis of the structural conditions favorable to the deposition of ore, together with sketches that explain the analysis graphically, is, in our opinion, the best way of helping the miner, more particularly the superintendents of mines and the consulting engineers who co-operate with them. It is 32 years since S. F. Emmons gave the Institute his paper on 'Structural Relations of Ore Deposits'; time and experience have tended to confirm the correctness of the quotation from Von Groddeck that served as the text for his illuminating suggestions. The German geologist said: "The obscurity which still veils from us the true nature of veins will become more and more cleared up when they can be considered in connection with the geological structure of the regions in which they occur." To this may be added the suggestion that the finding of ore will be increasingly facilitated by the study of the structural conditions more immediately

associated with the precipitation and distribution of the ore in the veins or other forms of deposit. The study of the ultimate origin of ores is interesting, of course, and for a time, marked by the publication of the treatises by Posepny and Van Hise, this question of genesis absorbed a large share of attention among mining geologists and engineers. We recognize that the ensuing discussion was valuable in establishing sundry fundamental facts, more particularly the character and circulation of the ground-water, but it must be confessed that in the enthusiasm of scientific inquiry the real purpose of mining, which is to find and exploit ore profitably, was not kept in view. We do not say that speculations concerning the origin of ore are valueless to the miner; on the contrary, they serve to sharpen his understanding and to quicken his observation, but, when all is said and done, it is much more important to the miner to be told where the ore is now than where it used to be; to be guided in his search for the geologically recent concentrations that he finds it profitable to dig rather than to be told the fascinating history of the chemical changes and devious migrations by which the ore was brought from unknown depths or unseen sources to the place where his pick strikes into it with a joyous whack. No mention of this subject of applying geology to the finding of ore can be made without reference to the deservedly popular handbook of Mr. J. E. Spurr, 'Geology Applied to Mining'. This *vade mecum* of the mining engineer was published in 1904, sixteen years after the famous paper by Emmons to which we have referred, and in large measure it may be considered its logical successor. Since he wrote his book, Mr. Spurr has demonstrated his own peculiar skill in deciphering the underground structure of several famous mining districts and has carried forward the Emmons tradition of making the science of geology the guide, philosopher, and friend of the mining industry. Just now the hope of a restoration of law and order in Mexico is awakening a revival of interest in Mexican mining affairs, therefore the articles by Mr. Lewis are timely. We shall be glad to receive notes or discussion on the subject from others familiar with conditions in the mining districts of Mexico.

Immigration

A bill is before Congress to bar immigration for two years, but it is not likely that any new legislation on the subject will be enacted just now. War regulations are still restricting the entrance of foreigners. The leaders of labor are urging a ban on immigration, while the leaders of capital are proclaiming that there will be a shortage of labor in the near future unless the gates are kept open. Most of us will be unsympathetic to such obviously selfish arguments; the problem is one of national importance and demands unbiased consideration. It is also a world problem. The admission of multitudes of foreigners may relieve the pressure of population in the countries of origin, but it is held by sundry economists that such emigration does not benefit those countries, largely because it stimulates an excessive birth-rate. The argu-

ments for restriction are various. Time was when we needed help from across the Atlantic in order to develop our surplussage of natural resources; our population was too small for our patrimony; now most of the immigrants go to the manufacturing centres, rather than to the land, either agricultural or mineral. Most of them crowd into our cities, it is said. Meanwhile some of our people view with alarm the prospect of a density of population like that of the congested regions of Europe, because it would involve a lowering in the standard of living and a degradation of the national type, for, just now particularly, there is a widespread desire to hasten the Americanization of the unassimilated foreigner, rather than to add further to the mass of undigested elements in our population. The question follows, how much should immigration be restricted? We have the Chinese Exclusion Act and the 'gentleman's agreement' with Japan. In 1917 the test of literacy was adopted by Congress, but it fails to exclude the most objectionable, namely, the half-educated unruly rejects of Europe, the men and women who too readily join the ranks of those that are opposed to any form of orderly government. An effort is made to exclude those manifestly diseased and those belonging to the criminal class, but complete discrimination is impracticable. Nor can we see how any tests can be devised that will be wholly effective. The advocates of restriction hold diverse opinions; some wish to exclude Asiatics; others, the Balkan peoples; some might carry their prejudice to the point of excluding Germans, or, dare we suggest, the Irish? Mr. Hearst, if he were logical, would bar the English from coming to a land their forefathers founded. Most ideas of exclusion when made specific are easily reduced to an absurdity. The most logical argument is that of the leaders of organized labor; they aim to exclude others like themselves in order to create a shortage of workmen and thereby increase the demand for their services. That is the expression of a perfectly intelligible policy based upon class-selfishness, but it has nothing in it that is patriotic in sentiment or national in spirit. It is true likewise that the capitalists desire to flood the labor market with the European horde, for reasons equally selfish. The professional class will detach itself from either party to the quarrel, preferring to face the problem with a larger mind and a more generous spirit.

What is best for the Nation? Shall the leading democracy of the world adopt a reactionary policy? What about the time-honored sentiment of an open door to the oppressed of every land? That generous policy had its political aspect, for it served to strengthen the young republic in the days when it needed greater security from foreign aggression. It had also an economic basis, for land was plentiful and an increase of population benefited all who were in the country. Another argument is that the incoming tide of humanity pushes itself underneath American labor and lifts it to a higher level, so that while the immigrant is bettered, our citizens are thrust into a more advantageous position. That reminds us of Francis A. Walker's statement that the great immigration during the thirty years preceding the Civil War

had the effect of causing a marked decline in the birth-rate of the native stock, so that at the end of the thirty years the population "differed by less than 10,000 from the population which would have existed according to the previous rate of increase, without reinforcement from abroad". General Walker was superintendent of the ninth and tenth censuses. He attributed the fact just mentioned to the introduction of large numbers of European peasants, creating distinct social classes and producing a complete change in economic conditions. The native stock went above or under, mostly above, acquiring a larger measure of wealth and leisure. With the improvement in social status came a restriction of the birth-rate such as is characteristic of the propertied class everywhere. Undoubtedly the foreign-born are more prolific than the descendants of the New Englanders and the Virginians. Those who gave us a rich heritage of democratic institutions are being displaced by the Slavic, Balkan, and Mediterranean peoples. But can we discriminate specifically against this or that race? It has proved difficult and dangerous, if not impracticable, as against the Japanese; could we discriminate, by legislation, against any of the European countries, more particularly the young republics created by the reorganization that has resulted from the War? If we could, would we? Would it not be better to face frankly the task of making the best of the incoming alien, by educating him to the point of American citizenship, meanwhile deporting those who are blatantly opposed to our institutions? Shall we not lose by stopping all immigration? After all, the American people consists of immigrants and their descendants. In President Wilson's cabinet were two immigrants, and the resignation of one of them does not depreciate his value as a citizen. Among the sanest leaders of labor there are two immigrants, Messrs. Gompers and Morrison. In every walk of life we find men that were born outside the United States and came here to find a career, useful not only to themselves but to the country of their adoption. Congress includes a large number of foreign-born, although the cynic again may smile and suggest that the argument is a weak one. Be that as it may, it remains true, as President Wilson said in his message of January 23, 1915. "Exclusion, adopted earlier in our history as a nation, would very materially have altered the course and cooled the humane ardors of our politics. The right of political asylum has brought us to this country many a man of noble character and elevated purpose who was marked as an outlaw in his own less fortunate land, and who has yet become an ornament to our public counsels." This is not particularly well expressed, but it is the utterance of a representative man, a student of our history and an earnest thinker. Are we threatened with a big influx of foreigners? We doubt it. Prohibition will serve to deter many from coming; the creation of new countries and the enlargement of opportunity in the young republics of Europe will hold many that might otherwise have come here. Let us face our social problems with courage, confident in our ability to solve them, rather than shirk the responsibilities that our destiny has imposed upon us.

DISCUSSION

An Interesting Experiment

The Editor:

Sir—The somewhat remarkable and unexpected results obtained in making an experiment with gold and quicksilver may be of interest to your readers. During a conference with E. W. Herrin, who is in charge of the gold department of Yuba Consolidated Gold Fields at Hammonton, California, certain questions arose as to the action of quicksilver upon gold, and it was decided to make an experiment.

In a small vial, 1½ inches high and having an inside diameter of ¾ in., Mr. Herrin placed an ounce of clean quicksilver, which filled the vial to a depth of one inch. A bar of nearly pure rolled gold, 2½ in. long, ¼ in. wide, and two thousandths of an inch thick, was placed in the vial and immersed in the quicksilver to a depth of ¾ in. The upper end of the bar was then bent over the mouth of the vial and left extending outward and slightly downward, with the end on a level with the surface of the quicksilver in the vial. In 43 hours the bar of gold was completely coated with quicksilver. In 168 hours quicksilver started to drop from its outer end, and a small dish was placed to receive it. In 720 hours half an ounce of quicksilver had been drawn from the vial, passed over the gold bar, and collected in the small dish.

The bar of gold before being placed in the vial weighed 6.2 grains. At the end of the 30 days it weighed 4.3 gr., 1.9 gr. having been dissolved in the quicksilver. Of this amount 1.68 gr. was found contained in the quicksilver remaining in the vial and 0.22 gr. was found in the half-ounce of quicksilver in the small dish.

It is possible that some of your readers may be able to explain the action that caused the quicksilver to be drawn from the vial and conducted over the gold bar. It is also interesting to note that in a similar experiment made under water the gold bar became amalgamated, but no quicksilver dropped from its outer end.

CHAS. W. GARDNER.

The Price of Gold

The Editor:

Sir—In your issue of March 6 last, the gold-producers of South Africa are congratulated upon having had a turn in their luck, and there is also a letter from Mr. Thomas French pointing out that Great Britain had been selling an ounce of gold for six sovereigns.

The gold question, as you say of exchange, has many facets, and though I am not capable of dealing with

many of them, I would like to call attention to one or two points that affect the gold miner.

There is a tendency to regard the premium on gold as unearned increment which gold miners are obtaining by some astute device at the expense of the rest of the world. Congratulating the producers of South Africa upon a turn in their luck, puts the matter in a very different light to that in which we see it. Owing to the exigencies of war, the British government, and practically every other government, found it necessary to control all traffic in gold. This control prevented gold from exercising its proper function in finance and undoubtedly contributed to the general rise in the price of commodities. Further, this control included the making of the paper currencies of various countries inconvertible, the direct effect of which is to displace gold from its position as a standard of value and make it just an ordinary commodity. During the course of the War every other commodity increased very largely in price, but the price of gold was fixed. The gold-producers raised no very loud protest, although production declined throughout the world to the extent of about 25%. After the Armistice, the Australian and South African gold-producers were able to make sufficiently strong representations to enable them to obtain access to an open market and thereby receive the real value of their produce, but this is hardly "luck"; it is only justice, deferred for some time owing to compelling circumstances.

Referring to Mr. French's letter, he draws some interesting conclusions, but his whole letter is based upon a misconception. He states that "gold is sold or exchanged in England in the best market and for this gold the producers now demand between £6 and £6.25 per ounce, *either in gold sovereigns* or their equivalent in other goods". The italics are mine. An ounce of gold fine can be exchanged for 4.25 sovereigns, and 4.25 sovereigns can be exchanged for an ounce of fine gold, for all practical purposes they are identical, the only difference being the cost of minting. When gold was quoted in London at £6 per ounce, it meant that for an ounce of gold you could get six British notes or a negotiable instrument of equal face-value, or the equivalent value in other goods, but six sovereigns could not be got for an ounce of gold under any conceivable conditions. Suppose, for the sake of argument, one could get six sovereigns for an ounce of gold; they would be immediately melted down, making an ounce and a half of gold, for which one would proceed to obtain nine sovereigns and this in turn melted into 2½ ounces would be sold for 13 sovereigns, and so on *ad lib.* It is exactly comparable to

the principal or perpetual motion, which, for some time past, has been held in discredit.

The question has a number of other aspects, but in order to follow any of them with advantage one or two basic facts, which are not difficult to grasp, must be recognized and the basis of the matter appears to be that

1. Gold is the accepted standard of value.
2. Gold is also a commodity and its price may vary if anything is done to interfere with its use as the standard of value.

3. War control of finance has so interfered and thereby caused the fluctuation in the price.

4. The price is expressed in the unit of measurement in current use and just now that is paper currency, not metallic currency.

5. Bar-gold of specified fineness and sovereigns or other gold coin are interchangeable on a fixed arithmetic basis only.

What is of interest to gold miners is the place that gold is likely to occupy in finance and in the arts for the next few years. There are so many conflicting factors that it is a somewhat hopeless task to attempt to find the algebraic result, but, looking at the matter broadly, it seems likely that the old basis, which took five years to destroy, is unlikely to be completely re-established in a shorter period, and as re-construction is a more difficult and longer job than destruction, gold-producers can reasonably expect that a substantial premium may be got for even a longer period. On the other hand, the gold miners, like everyone else, would quite gladly see the price reduced provided that there was a general return to something approaching the normal trade conditions of the good times before the War.

Geological Experts in the Courts

The Editor:

Sir—Referring to your recent discussion of the above subject, I venture to quote from my paper, published in 1917, on 'The Extralateral Right', in which I suggested a remedy for a state of things that has recently given rise to much well founded criticism.

"As a matter of fact the objection that experts employed in mining litigation become advocates can be met in another way and valid criticism based on the expense of extralateral trials overcome to a large extent by reform in the present objectionable methods of handling such cases.¹ It is admitted that the reform would have to be radical but it is worth considering, for the extralateral right is bound to be the subject of adjudication in the future, as in the past, at least, as far as existing vested rights are concerned.

"In each State there should be a provision added to its laws whereby a judge, specially qualified to try extralateral cases, could be called in to sit where such rights

are involved. To the average judge an extralateral suit is like so much Greek and a large portion of the trial is taken up with educating the court on the elementary principles involved. Most of the mining laws of other countries recognize the fact that mining cases involve technical problems that cannot be satisfactorily and intelligently adjudicated by the regular courts and, consequently, in practically all foreign countries a special tribunal is established to try mining cases.² In some countries jurors, even, are required to be experienced in mining.

"Another objectionable feature which can be readily improved, is the present method of employment by each side of an army of experts.³ Practically all extralateral cases resolve themselves, sooner or later, into a battle between opposing experts. This results in great expense as well as confusing exaggeration of structural details of minor importance. In a great majority of cases justice could be as readily obtained by a board of experts, one to be selected by each side and a third by the judge of the court, the expense to be shared equally by each party. These experts could examine the properties involved and make a report on the geological occurrences. They would agree on most facts, and where there was a difference of opinion litigation work could be ordered to further develop the points of difference. This plan would eliminate much of the expense and time consumed in such trials. The court would accept the facts agreed on as proven and confine the trial to disputed issues. This plan or some other framed along similar lines would do much to remove the stigma of an excess of expensive litigation to which the extralateral right is now properly subject. It would tend to minimize the existing evil which will still continue to abide with us in the case of all existing claims and would obviate a plunge into untried dangers and hazards which are bound to follow a radical change in our present law.

"If it is litigation we wish to avoid, then why not also take up the question of compelling all locations in the future to conform to legal subdivisions.⁴ By requiring lode-claims to be located in conformity to public-land surveys as is now required in the case of placers and also by registering all locations in the land offices, it will readily be seen that a vast amount of litigation arising by reason of conflicting surface-rights would be elim-

²Any one who was familiar with the trial of mining cases in the federal courts before judges like Hawley or Hallett, who thoroughly understood these technical mining problems, will appreciate the great saving of time and expense which would result from the trial of technical cases by a specially qualified judge.

³The employment of experts in extralateral litigation is not an unmitigated evil. In many cases orebodies of considerable value have been encountered as a direct result of litigation work or suggestions of the experts and in many mines the geological conditions are slighted and but poorly understood until an extralateral suit is instituted and then the first scientific information of value is obtained concerning a mining camp.

⁴This is not a novel suggestion. See Trans. A. I. M. E., Vol. XLVIII, p. 422.

¹As Charles Shamel says: "The fault lies not with the apex law, but with the existing instruments and methods of legal procedure." Trans. A. I. M. E., Vol. XLVIII, p. 34.

inated. An amendment of the mining law as suggested would eliminate tenfold as many cases as would be eliminated by abolishing the extralateral right. But by each of these remedies the advantage of economic operation of the ore deposit as a geological unit would be sacrificed. The vein on its dip into the earth has nothing in common with the surface and to parcel it out by surface area and vertical boundaries is a structural misfit and so would be the forcing of lode-locations into rectangular surface-areas conforming to the public-land surveys. Such reforms are ideal from the standpoint of minimized litigation but entirely impractical from the standpoint of the most economic mining of the ore deposits."

San Francisco, June 4.

WM. E. COLBY.

The Bunker Hill Tramway

The Editor:

Sir—In your issue of May 15 is an article, No. 9, by Mr. T. A. Rickard, entitled 'The Bunker Hill Enterprise', in which he refers to the aerial tramway the equipment for which was furnished by the Trenton Iron Co. for the Bunker Hill & Sullivan Mining & Concentrating Co. in 1891. The statement is made that owing to defective design it proved a very expensive and troublesome affair, due to dropping of the buckets from the line, which resulted in the killing of persons in their homes and horses in the street.

The carriers of this line were equipped with grips of German design, and were attached to the traction-rope by means of lugs fastened to this rope at definite intervals, which engaged with the grip-forks, between the prongs of which there was a slight play, and I believe some trouble was experienced at the outset by the slipping of the lugs, which was finally overcome by what is referred to in the article as a "new type of button".

The original design, I know, contemplated a brake-station in the valley where the town of Wardner is located, and this I believe was in conformity with the wishes of the officials of the Bunker Hill company who had charge of this installation, and I have no doubt that trouble may have been experienced owing to the uplift of the traction-rope. I was informed of one woman being killed while asleep by a bucket discharging its contents through the roof of her home, an accident such as might happen to any new machinery of this kind. If other persons and horses were killed by the dropping of buckets, the present writer, who was instrumental in the design of this tramway, was not before aware of the fact.

The line was operated many years before it was finally superseded by the adit referred to in the article, and to the best of my recollection it was amply capable of transporting the amount of ore—50 tons hourly—for which it was designed. Far from being the conspicuous failure that the paragraph in the article referred to would lead one to believe it was, the Trenton Iron Co. did not hesitate to refer prospective customers to this installation, and to exploit it extensively in their advertisements, a view of that portion of the line showing the long span—

1173 ft. across the town of Wardner being shown at a frontispiece in their book on aerial tramways. The reputation obtained through this line, I have reason to believe, resulted in other contracts being secured for similar lines.

I have been unable to locate the original profile, but since the span across the town of Wardner was 1173 ft., I cannot understand the reference to a span of 1100 ft. in the original design. The length of the line, according to the records at this office, was 9000 ft., not 10,000 ft., and assuming that Mr. Rickard is correctly informed as to the total cost, this must have been about \$10 per foot, which appears to be excessive for that time, and I am inclined to believe is mainly due to the changes rendered necessary by the condition stipulated at the outset of having a control station at the town of Wardner.

Pittsburgh, May 23.

WM. HEWITT.

The Case Oil-Fired Assay-Furnace

The Editor:

Sir—Mr. Borzynski's article on this subject in your issue of May 15 is full of interest.

To secure the best results in cupelling, experience has shown that the air to the burner should be cut down very low. At first thought this seems contrary to theory as in cupelling one naturally desires maximum oxidizing conditions. Perhaps by cutting the air down (and regulating the temperature by the oil-valve alone) there is less back pressure in the combustion chamber and less reducing gas forced into the muffle, but whatever may be the theory, by using this method, it is possible to feather seven or eight rows of cupels beautifully.

This type of furnace has been much improved recently: by using the new DFC burner, the regulation of both oil and air is made convenient and positive. In the new type, the enclosed hood probably assists the draft through the muffle.

Denver, June 7.

J. CLAIRE EVANS.

Gold in North-Eastern Siberia

The Editor:

Sir—Your editorial note, in the issue of June 5, stating that "north-eastern Siberia is not a country rich in gold" agrees with the information that I gathered while exploring that coast in 1900. Rumors of rich deposits in that region were current in London and I was given a steamer and a gang of workmen and sent to investigate the coast opposite Cape Nome. After learning from a whaling captain that a party of Americans had been digging ditches, presumably for gold-mining, at St. Lawrence bay, we were quite hopeful, but on arrival we found the work had been done by men who had come over from Alaska to buy reindeer. Prospecting parties of workmen under my charge found not even a color of gold. The chief of the Russian expedition that was also studying the region in 1900 told me that he had found two colors of gold, but he was unable to show them to me, as

they had been lost. Some of the American engineers who were with this Russian expedition could give interesting information about these gold discoveries and other incidents of that voyage.

Since 1900 Russian prospectors have examined the country and a sketch-map in a Russian pamphlet published in 1916 shows 30 localities in which gold had been found. The pamphlet states that while prospectors are sent to prison as 'poachers', development is handicapped. No evidence is given of any gold discoveries warranting a stampede. What the attitude of Lenin and Trotzky is regarding this region is unknown, but it seems most

used, although one make had a fair sale before the War. It is said, however, that a large proportion of the pumping on the Rand is done by American machinery.

The 'M-Z' Automatic Mine Car

By O. J. ZOOK

Mine cars of approximately one-ton capacity are used almost invariably in metal mines in the West. They must be designed to be readily dumped, and the increased use of electric motors for underground haulage

THE 'M-Z' MINE-CAR AS MADE BY THE BUTTE & SUPERIOR CO. FOR ITS OWN USE

likely that American prospectors would meet an unpleasant reception.

Palo Alto, California, May 9. W. H. SHOCKLEY.

The production of rolled zinc in the United States in 1919 declined over 20% in quantity and 45% in value as compared with that in 1918. The percentage of loss in quantity was greatest in boiler-plates and heavy sheets, amounting to more than 60%, but there was a loss of nearly 30% in ordinary zinc sheets. The output of zinc strips, on the contrary, was slightly greater than in 1918. The losses were apparently due to the cessation of the demand for zinc for war uses. The principal producers and rollers of zinc, working through the American Zinc Institute, are endeavoring to find and establish new uses for rolled zinc and to extend the present uses. The substitution of sheet zinc for sheet copper and brass and for tin-plate, wherever possible, is urged, and likewise the substitution of sheet zinc for galvanized iron or other sheet metal in roofing, gutt-rinz, spouting, garages, refrigerator linings, household utensils, and hospital ware. The use of sheet zinc for roofing seems to offer the most promising field for expansion.

PUMPS of Swiss, British, and American manufacture are used throughout the Johannesburg district of South Africa. The Sulzer is said to be the most popular of the pumps manufactured in Switzerland. Those imported from England include the Climax, Tangye, Allen, Pulsometer, Pearn, Robeson-Davidson, and Rees-Roturbo. German pumping machinery has never been extensively

makes it necessary that special attention be given to the construction of coupling and bumping devices. Another important point is that the car can be manipulated with the least possible danger to the miner. During the past 20 years very little improvement has been made in the design of mine cars except for the adoption of roller bearings for the wheels. The accompanying illustration shows a car which has been developed by O. J. Zook and Charles Marshall at the Butte & Superior mine at Butte. The following features of the 'M-Z' car, as it is called, will appeal to those who are familiar with the difficulties met in the use of the ordinary car.

1. Nothing projects from either end of this car to be broken or bent when cars are bumped together in motor haulage.
2. The door is unlocked and locked automatically.
3. The body of the car is released from the truck, for dumping, by a foot-lever. The foot-lever does not project beyond the end of the truck frame.
4. The shackles for coupling the cars can be removed by taking out two cotter keys, which simplifies their removal when repairs are needed.
5. The repairs will be cut to a minimum by eliminating the hook-rod, and levers that are used on the ordinary style of car, and which cause 75% of the repairs.
6. The door will not 'hang up' due to the hook-rod being bent by bumping together. Accordingly the car cannot go over the dump or into the chute when being dumped.
7. Less than one-half of the time is required to dump the 'M-Z' car than is required with the ordinary type.

The Ore Deposits of Mexico—III

Non-Contact Deposits in Sedimentary Rocks

By S. J. LEWIS

INTRODUCTION. We now pass to an economically important class of ore deposits, chiefly in lime-shale, in which the part played by the associated igneous rock is of considerably less importance than in the preceding. In the typical mines, the shale is underlain by an intrusive, generally a rather basic andesite, and is heavily folded and broken, with important faulting of the ore-bodies after formation. Not necessary to the type, but

of the El Oro district are the best examples of this class. While their geologic features are well known to mining men interested in the district, they have not been fully described for publication, and it will therefore be allowable to summarize the most important features before going on to less-known examples.

The Cretaceous lime-shale, deposited over a large part of the Central Plateau, from Chihuahua through Du-

FIG. 10

frequently occurring, is a cap of andesite or rhyolite over the shale, earlier in time than the ore deposits, that has usually been of great importance in protecting the veins from destruction. The mineralization follows nearly vertical fractures traversing both the sediments and the underlying andesite, but usually becoming smaller and tighter in the latter; the orebodies are usually confined to the sediments, the ore becoming scarcer, lower in grade, and more associated with base sulphides where the fissures have entered the andesite.

EL ORO-TLALPUJAHUA DISTRICT. The gold-silver mines

rango, Zacatecas, Guanajuato, and Queretaro to the States of Mexico and Hidalgo, was covered in early Tertiary time by a series of andesite flows of a considerable total thickness. Prior to this the topography had been deeply carved by the usual agencies, so that the andesite cap filled some old hollows and is thinner on old peaks. There is no evidence of mineralization of the shale to an important commercial extent till the returning volcanic activity of Miocene time brought the green andesite intrusives, which pushed their way into the shales horizontally, as laccoliths and sills. The disturbances to

the sediments due to these intrusions, as well as to subsequent cooling, caused extensive fracturing in both, nearly always as continuous fissures going through all the rock-members of the formation. Mineralizers issuing from the intrusive mass have reacted with the carbonaceous matter in the shale, depositing extensive bodies of silver-gold ore. These have then been cut by cross-fractures, causing a re-opening of channels and a circulation of mineralizing waters, so that secondary enrichment is an important factor in these deposits. The gold-silver ratio varies considerably; in some mines the amount of the silver is equal to that of the gold and there is therefore a great difference in their value; in others the money values of the two metals are about equal.

Perhaps the most useful structural basis for study of this class of deposits would be the change suffered by the mineralization in passing through the different kinds of rock that the fractures have cut through. The cap, which existed prior to the fracturing, has been faulted, but not mineralized. Nevertheless, the presence of a protecting cap on the deposits has been important, not only in saving them from destruction from surface agencies, but also for fundamental geological reasons. Circulation limited on the upper horizon means heavier deposition within the shales. There must have been, also, a difference in the origin of the fractures, due to the cap. Shale is not easily fractured in the mass, though brittle in small pieces; it yields to dynamic stress, bending with surprising elasticity, taking up movements and shocks, and closing behind them, leaving a bend instead of a crack, as in the more rigid limestone. There are no such enormous fractures and cave-openings in shale as are found in the limestone; only poorly defined circulation channels, albeit extensive ones. In the Central region, where the shale was capped by a sheet of andesite, the fracturing was stronger, owing to the resistance of the more rigid rock. The strata were twisted and torn out of place, with strong and extensive up-and-down movement of the fracture-walls, so that important circulation channels resulted, the adjacent shale being well shattered or loosened, and thus prepared for reaction with the elements of mineralization.

At El Oro, the three important rock factors are, beginning at the surface: the early andesite, purple-red in color, covering the El Oro deposits but eroded off the Talpujahua side, and varying in thickness from 90 to 810 ft., depending on the old topography. Next is the shale, from 500 to 900 ft. thick, black, thinly laminated, with every conceivable local variation in dip, and traversed by numerous quartz-filled fractures, some of which have become ore-veins. Below the shale is the green or recent and-site, occurring as a sill, in which profitable ore has not been found, about 1000 ft. thick; and finally, at a depth of 2200 ft. below the surface, the shale has again been encountered recently, with the natural hope of finding another enrichment.¹⁵

The Talpujahua half of the district lacks the cap over most of its area, and it may be noted, the silver content is of considerably more importance there than at El Oro.

At the extreme southern edge of the area occurs an interesting and extensive zone of brecciated shale, in which a little gold has been deposited, making a stockwork in which silicious solutions have circulated.

The most significant feature of the district is the large-scale faulting, which took place after the formation of the whole fracture system. See Fig. 11. Two heavy parallel fault movements, about a mile apart, traversed the ground nearly due east and west, cutting out a long and narrow fault-block, of which the Somera mountain forms today the high point. This fault-block was pushed up, and was attacked by agencies of erosion and degradation. The cap was worn away on the eastern and western slopes, making drainage lines of today. On the Tultenango or east side, we have a country of shale and clay soil, lacking ore deposits so far as known; on the west or Talpujahua side, the cap is gone except on the raised fault-block, leaving the shale of the Borda group entirely bare, for a long distance, well into Michoacan. As long as the miner remains in the fault-block in that region, he is in shale; as soon as he steps across either the north or Reforma fault or the south or Victoria fault, he finds himself again in the andesite, with hundreds of feet to go through before piercing the shale. Up to the present, prospecting in the shale outside the fault-block has been fruitless. It is only within the shear-zone formed in the fault-area that the mineralization has gone far enough to render exploitation profitable.

The veins, numerous and nearly parallel, run north-west, nearly at right angles to the direction of the great faults. The primary mineralization was performed by alkaline solutions, precipitating principally lime, and carrying little of the precious metals. Later disturbance caused considerable cross-faulting of these veins, enabling the re-entry of mineralizers. These solutions were highly silicious and rich in the precious metals. They circulated in the lime veins for long periods, thoroughly searching them, replacing with silica the minerals already formed, and enriching the deposits. That this replacement was carried out in great detail and perfection is conclusively shown by numerous pseudomorphs of quartz after calcite, beautifully formed, found in all the veins; that is, crystals which have every appearance of being calcite, but in which every particle of lime has been exchanged for one of silica, the original shape being preserved.

With the wearing away of the cap, and the circulation of surface waters in the cross-fault channels, secondary enrichment and oxidation came into play, and made the deposits of the Esperanza, El Oro, and Mexico mines, remarkable for both extension and richness, accompanied by extreme irregularity both in the occurrence of the ore-bodies and in the distribution of their valuable contents. Fig. 10 shows the general relations of the rock-members and veins in these deposits.¹⁶

We have then, in these deposits, at least three well-defined stages of mineralization, similar to those that were noted in the mines of the San Pedro district: first, a primary alkaline mineralization, depositing calcite crys-

¹⁵Courtesy of A. F. Main, El Oro M. & Ry. Co., Mexico City.

¹⁶Annual report, El Oro Mining & Railway Co., 1913.

FIG. 13. SECTION FROM ZACUALPAN TO SULTEPEC

tals in more or less open channels, with low gold content; second, later silicious mineralization, coursing through the same channels and replacing the lime, which silicious solutions introduced important amounts of the precious metals; and lastly, the coming in of meteoric waters due to the penetration or removal of the cap, and consequent oxidation and secondary sulphide enrichment. The cap, by eliminating the influence of surface agencies at least during the early part of the life-history of the El Oro deposits, narrows the problem of origin of mineralization down to emanations coming out of a deep-seated igneous

source, wholly within the limits of the fault-block.

It cannot be said that the association of the intrusive with the ore deposits is as intimate in the case of the El Oro examples as in that of a true contact deposit like Barreno; it is, however, sufficiently obvious that the intrusive furnished from its magmatic emanations at least the rudiments of the deposits. The fact of the shale forming the horizon of deposition practically to the exclusion of the underlying andesite, suggests comparison with such a true contact deposit as Ajuchilán, where precipitation of metallic salts from magmatic solutions took place, never immediately on the contact surface, and never inside the intrusive, so far as known, but always in a zone from 25 to 50 m. removed from the contact, and hence wholly within the shale. See Fig. 12.

SULTEPEC-ZACUALPAN DISTRICT. Less known examples, but very interesting ones, are to be found in the Sultepec district. For reasons that will suggest themselves, the names of some of the properties concerned in the following discussion will not be given. See Fig. 13.

The El Oro shale continues south into the State of Guerrero, with local interruptions, and with the same or a similar intrusive underlying them. There is, generally speaking, no cap. The intrusive is the same green andesite, which has pushed its way into the shale strata for long distances, reaching its highest point of elevation in the Zacualpan district. The shale, from 300 to 600 m. thick, is cut by numerous fracture-systems, in which quartz, calcite, and most of the base sulphides have been deposited, with varying amounts of silver and sometimes considerable gold.

The history of mining development in this shale has thus far been practically the same. Rich gold-bearing silver ores are found in pockets near the surface, which continue down in the form of chimneys till the andesite is reached. The veins then become impoverished, and the fractures generally, though not always, diminish in size, usually tightening considerably. Occasional spots of enrichment are found, carrying clean crystals of argentite, stephanite, and the ruby-silver minerals, but as yet no real orebodies have been developed at this horizon. In one of the extensively developed mines of the Sultepec district, pyrite ores carrying gold as the principal metal, but with an appreciable silver content, occurred in long bodies over several hundred metres of

FIG. 11. THE EL ORO-TLALPUJAHUA FAULT-BLOCK

lateral development, in the shale. Exploration downward on these ores has reached the andesite horizon and a certain amount of work has been done to a depth below the shale of about 200 ft. So far there have been no favorable developments. In another mine, near the Indian village of Mamatla, in Guerrero, about half-way

surface. Meantime, sinking on the orebody was carried on from the tunnel-level down toward the andesite. In spite of a slight enrichment at the horizon of change, it soon became evident that the ore was becoming poorer, and after about 25 m. of sinking, with the vein still strong, the ore practically disappeared. Confirmation

FIG. 12. SKETCHES OF INTRUSIONS AT AJUCHITLAN

between Sultepec and Zacualpan, the geologic conditions were worked out with great exactness with the same result. An enriched pocket, in the shale, yielding exceedingly high-grade silver ore with some gold, was discovered by means of a tunnel about 40 m. above the andesite, which outcrops in contact with the overlying shale on the steep hillside. The ore was stoped upward until *antigua* workings on the same chimney were reached, the mineralization being continuous up to that point and having formerly existed from there to the

was sought by utilizing an old opening below, entirely in the andesite. This was carried forward to a point below the workings mentioned, the veins persisting and showing an occasional lump of rich and clean ore of the type found in the Zacualpan district proper, but as a whole the exploration was unproductive and had to be abandoned.

A more striking example of the same facts, occurring at the edge of the Zacualpan district, but geologically still in the Sultepec formation, is to be seen in the case

of a certain *antigua* that became the object of a well-known local stock-flotation. An expensive mill was erected to treat the ore remaining from former operations, prior to development in depth. The known orebodies were entirely in the shale just as in the cases described. When milling began, sinking on the old orebodies soon reached the andesite, with such an impoverishment as to make the operation unprofitable. The enrichment had clearly been only in the shale, of secondary nature, and the former workers had thoroughly understood the conditions and confined their operations to the shale.

The conditions in this and adjoining mines are complicated by the presence of recent dikes of a dark basic rock, very hard, and from one to ten metres thick, which cross the older veins at acute angles and with about the same dip, that is, from 60° to 75° . These dikes have brought in considerable iron sulphide and some copper, which in the case of a few intersections occur in small orebodies. On the whole, the dikes have not been a benefit to the deposits.

The most important property in this particular area, and one frequently mentioned locally as being in the Zacualpan district, is the old Carboneillo, out of which a notable orebody was extracted beginning about 15 years ago. The occurrence illustrates perfectly the conditions under which enrichment is likely to take place in the mines of this area. There are four principal veins in the mine, all from 50 cm. to a metre wide, all vertical in dip, and coming together at an acute angle under the old caved workings of the surface. A cross-cut tunnel was driven to cut all the veins and a little ore was taken out in exploring them, in small lenses; nothing of importance, however, was found until one of the workings was driven toward the intersection of the veins. An immediate improvement in width and grade ensued, and the ore was followed into a rich orebody, from which for several years good ore was taken out. These orebodies were entirely in the shale.

Study of these typical cases, with the intermediate variations that occur in the district, has convinced me that while exploration in the andesite is necessary and well worth while, a barren zone certainly occurs in the andesite immediately at its contact with the shale, and that the probabilities are rather against finding orebodies of any size at great depth. Ore can be found, but the veins change their character and the mineralized spots are few and far between. The fundamental principles of ore deposition which we have been following in these examples show us that where fractures diminish in size with depth and the formation becomes drier and tighter, it is not likely that favorable conditions obtained for the deposition of mineral from solutions.

ZACUALPAN DISTRICT. If we follow the above formations into the Zacualpan district proper, we find the shale subordinated and the mineralization strongest in the andesite, and this without any break in the continuity of the intrusive; that is, the enrichment that in the one district takes place in the overlying sediments, in the other

takes place in the underlying andesite. The difference is largely physiographic; much of the enrichment in both areas is secondary in its nature, depending on the circulation of meteoric waters along the fractures. Where the andesite is deeply buried, secondary enrichment has not reached it to an appreciable extent; where, as in the Zacualpan district proper, the andesite pushed its way to the surface, mineralized fractures in the formation have been affected by secondary enrichment and valuable orebodies formed. As this area comes under the classifi-

FIG. 14

cation of ore deposits in eruptive rocks, I shall leave its discussion for the present. The characteristic changes that appear in tracing the orebodies from the shale through the andesite, make the district a most interesting one to the student; and it has been for three hundred years not less so to the miner, having maintained an intermittent production from Spanish times to the present, without important outlays of capital.

BENITO JUAREZ DISTRICT. An interesting example of mineralization in shale influenced by a near-by intrusive is to be found at Salinas, in Zacatecas, in the Benito Juarez mines. These gold-silver veins occur in shale, considerably disturbed, near Salinas, where the famous salt deposits are situated. The most prominent topographic feature of the district is the Peñon Blanco, a high mountain five kilometres from the deposits. Peñon Blanco is composed entirely of a light-green andesite, which has pushed through the sediments after the first fractures had formed, and has caused the re-opening of

ground by a second series of cross-fractures, making an angle of about 60° with the first group. This second system of fractures has a strong quartz filling, with highly enriched gold ores at the points of intersection with the older veins. Outside the intersections, the gold contents are low, sometimes for long distances.

Between these mines and the Peñon occur a few prospect holes on the quartz veins, showing much purely secondary mineralization such as is found in contact deposits. If some of these fractures could be followed down, they would probably show contact with some intrusive body connected with the Peñon mass. As it is, there seems to be no doubt that the gold in the Benito-Juarez veins came from recent silicious solutions having their origin in this intrusive mass, and making deposition at such a distance from it as to appear independent of intrusive influence.

COMBINATION FORMS. An extraordinarily interesting series of ore deposits is found at Catorce, in San Luis Potosí; in these all the features of deposits in sedimentary rocks are combined with a continuation of the fractures and the ore into the underlying andesite. The district is one of the oldest in Mexico and has been productive of high-grade silver ores, the old Concepción, La Luz, and San Agustín mines having been important for generations.

The Catorce formation is made up of three principal rock-members; first, the blue Cretaceous limestone, in which the veins have formed large irregular pockets and in which the early miners found their bonanza ores; second, the dark andesite underlying these sediments and forming the foundation of the Catorce uplift, which reaches an elevation of 9000 ft. above sea-level. The silver veins of the district, from half a metre to several metres wide, go down through the limestone into the andesite and have been worked for several hundred feet below that horizon. Finally, both limestone and andesite have been intruded by numerous dikes, usually cutting obliquely across the veins. These igneous dikes, known as 'porphyry' in the district, are from a few centimetres to several metres thick, of a more silicious nature than the andesite itself, but presumably an end-product of the same magma that made the andesite. I have not determined the dikes petrographically. That they have had an enriching influence of the highest importance, seems to be indisputable. The silver veins are not enriched sufficiently except near these dikes, there being long stretches of nearly barren ground between the inter-

sections. Approach to a dike in the course of exploration is nearly always accompanied by a rise in the grade of the vein-filling, as well as by increased width of mineralization, and all the high-grade orebodies have been found close to the dikes.

The andesite is an enormous mass, affecting the whole district for miles around and plainly visible on the surface in the immediate neighborhood of the Real de Catorce underlying the limestone. The sediments have been worn away into rounded light-colored caps on top of the darker igneous rock, so that the structure is readily visible from a distance. The limestones are 300 to 500 ft. thick; the andesite, from 1000 to 1500 ft. at least, probably going still deeper. The whole uplift rises out of

FIG. 15. PLAN OF PADRE FLORES MINE

the detritus of the Catorce plain in abrupt fashion, making a mountain wall that extends about 15 km. south to the Wadley antimony deposits, which must be regarded as within its zone of influence.

PADRE FLORES MINE. The accompanying drawings (Fig. 14 and 15) show workings in an old silver mine of the district, to which tradition assigns a fabulous production during Spanish times. The section shows the relations of the vein-fractures to two different country-rocks, as well as to the near-by dike. The old stope is an impressive sight from the San Cayetano workings, which enter it high above the floor; it is in all respects similar to the great caves of the Barreno and similar lead mines, being a long, rambling, irregular chamber in the limestone, formed by extension of replacement from a central fracture across the bedding of the strata, and going down almost vertically. It is about 100 ft. long, 60 ft. wide, and about 250 ft. deep, its bottom being lost in the zone of decomposed white material found at the contact of the limestone with the andesite. From the chamber itself go off old workings on the strata in a few places, where

during the period of mineralization the limestone offered favorable conditions for the formation of replacement orebodies. Such was evidently the San Cayetano working through which one enters the chamber from the surface. The great stope and its subsidiary bodies have all the characteristics of the true contact orebodies: size, shape, position with reference to the andesite, and relation to mineralizers coming from the latter, as well as the fact that the ore carried considerable lead and some zinc.

The vein associated with this remarkable orebody was followed down to a depth of over 300 ft., the mineralization being about a metre wide and yielding a little ore. It has never, however, in any degree approached the magnitude of the old *Salón del Padre*, and the very heavy flow of water, to be handled only by the best modern pumping machinery, has hindered further exploration in depth, just as it has in the more important properties of the district. In these, however, while the orebodies in the limestones were also of much more importance than those in the andesite, the latter have been profitable; in such a mine as *Concepción de Catorce*, for example, the vein is several metres wide even in the andesite, so that in spite of the undoubted diminution in width and value on entering the lower horizon, it has been possible for the larger mines of the district to operate profitably at depth, even though handicapped by the strong flow of water.

SUMMARY. There seems to be no doubt that in this district, more favorable conditions for deposition were found in the sediments than in the andesite, in which respect it is like the ore deposits we have just been studying; but unlike those, the enrichment in the Catorce deposits has continued into the igneous rock for great depth, making mining profitable in the andesite also. To what depth the mineralization may extend is not known.

The difference between these deposits and those of the shale in the *El Oro* and *Sultepee* districts is therefore a great and a vital one. The most obvious difference in structure is the presence of the numerous porphyry dikes and their undoubted influence in enriching the deposits locally. In *Padre Flores*, for instance, where but one important orebody was found, only two dikes have been observed; whereas they are numerous in all the better-known mines of the district. It may well be that these porphyry dikes, undoubtedly a later separation from the same magmatic structure out of which came the mineralization of the veins, may have re-established a connection with the interior of the mass, re-opening the partly mineralized veins, and bringing in later the silver-bearing solutions that attacked the andesite in somewhat the same manner as the limestones. This would depend largely on the nature of the andesite, which is totally different from the green eruptive of the *Sultepee* district, although certain alteration phases give it the same color. The unaltered rock is similar to the reddish-purple andesite of the *Huotipaquillo* region in *Jalisco*, in which important silver mines exist.

A MIXTURE of 70.3% antimony, 21.2% sulphur, 1.14% iron, and a trace of silica—the whole being the resultant

product of ore which has been subjected to the process of metallic fusion known as 'liqiation'—constitutes material containing antimony and is dutiable under paragraph 144 of the tariff act, according to a recent ruling of the Board of Customs Appraisers.

Diamond Mining in Africa

Diamond mining is the principal industry in South-West Africa. Diamonds were first discovered in 1908, during railway construction, in the valley sands of the coastal desert, and have since been recovered over a stretch of 270 miles between latitude 28° and 24° S. However, there are wide intervals where no stones have been found, and none have been discovered at a greater distance than 15 miles from the coast. Various theories have been advanced as to the origin of these diamonds, but the theory to which facts appear most satisfactorily to lend themselves is that the diamonds are of sea origin. It is generally believed by geologists that primary deposits exist under the sea within the area between Possession island and Pomona on the mainland. The stones already found by dredging in the sea are believed to have been thrown up on the floor of the ocean by volcanic action, while the stones on the mainland, according to this theory, have been washed up and carried by the wind in the drifting sand dunes. Another fact which geologists believe substantiates their theory is that the largest stones hitherto found have been picked up just south of Pomona, which indicates that the centre from which the gems were distributed is situated in closer proximity to the southern part of the Pomona claims than to any other section of the fields. Taking everything into consideration, they are led to believe that the South-West African diamonds have been derived from primary deposits that lie buried beneath the sea somewhere in the neighborhood, and evidently to the south, of Pomona. Experts are agreed that the diamonds are unlike those of any other known source—primary or alluvial—in the Union of South Africa. This view is endorsed by the Antwerp and Amsterdam cutters, who maintain that the stones in hardness and other physical properties more closely resemble the product of the Brazilian fields. They are characterized by great brilliancy, even in the uncut state, and the quality is remarkably good. This accounts for the fact that, notwithstanding their diminutive size, great numbers of these stones have been absorbed by the world markets. In weight the diamonds range from 1/20 to 34 carats. The average size of diamonds produced in 1913 was $\frac{1}{2}$ carat. The largest stones have been found in the Pomona and *Ida Tal* area. As regards color, diamonds of almost every conceivable hue are represented. Blue-white stones occur, but are on the whole rare. On the other hand, clear white crystals are very common and make up the bulk of the output. Many yellow, pink, dark red, purplish, bluish, green, and black stones are also found. During 1913, the last full year before the War, the production amounted to 1,284,727 carats, valued at \$13,132,250.

FIG. 2. NET PRESSURE, 0.50 INCHES

FIG. 3. NET PRESSURE, 1.50 INCHES

FIG. 4. NET PRESSURE, 3.50 INCHES

FIG. 5. NET PRESSURE, 14.00 INCHES

chart ruled in one-inch squares with white ink was substituted and clear distilled water was employed instead of equal-scent water. The accompanying photographs were taken at a speed of 1/260 of a second with a special Gradex camera. They compare the action of bubbles under pressures of air varying from 0.50 to 14.0 in. of mercury, the latter being much higher than is used in practice. The term 'net pressure' refers to the amount in excess of that necessary to displace the water in the cell and overcome the resistance of the apparatus, which amounted to 2.35 in. of mercury. In milling practice the pressures range from 8 to 10 in. of mercury (4 to 5 lb.), including the pressure that is necessary to offset the hydrostatic head and the resistance of the air between the pressure-gauge and the outer surface of the canvas, which will vary from two to four inches of mercury. Some of the pressures used in this experiment are well within the limits of practice, while others are much higher than would be used in a cell.

RESULTS. These experiments conclusively prove that there is no difference in the velocity of the bubbles due to any increase or decrease of air-pressure within the limits ordinarily employed in milling. Attention is called to the photographs: a close inspection of them, particularly the lowest one-half inch of the canvas, reveals no sign of a horizontal path of the bubbles. None shows any horizontal component of force, or that force which would give the bubbles an initial velocity. Any departure of a bubble from its natural vertical path is caused clearly by the crowding of a larger number of bubbles extruded under the higher pressures.

In the case of a pneumatic flotation-cell, the porous medium, whether it be canvas, porous brick, or cement, acts as a fine subdivider for the air and also to some extent as resistance. Microscopic examination of the canvas used in this experiment shows that there is on an average about 1000 holes per square inch available for the passage of air between the threads of the fabric. The pressure from the air-blower forces the air in fine streams through these less resistant parts of the porous medium. Where a decidedly low pressure (Fig. 2) is used only some of the most easily penetrated holes in the medium act as conduits for the bubbles, and as the pressure is increased this number becomes correspondingly greater.

As these streams of air emerge into the water they form bubbles that are released individually from the rest of the air, when the buoyancy of the water is greater than the surface energy required to form the bubble. It is evident that if the working-pressure of the cell is doubled, twice the amount of air will pass through the canvas. As the pressure is increased within the limits of usual practice the number of bubbles is correspondingly increased. It was also noticed that bubbles rarely combine to form larger ones, but seem rather to repel each other. The photographs illustrating the higher pressures show the formation of so many bubbles that there is crowding and a tendency to shove some of the bubbles half an inch or so away from a vertical path. The extreme pressures, observed in some of the experiments,

caused a violent 'bumping' at the surface; and it is quite possible that some of the small bubbles collide, join together, and form larger ones. While it is true that these larger bubbles do travel upward with a greater velocity, there is no initial velocity. Such turbulent action would be unsuitable for the flotation of mineral. It is evident that this horizontal displacement and crowding cannot be mistaken for a horizontal component of velocity.

The object of photographing the paths of the bubbles was to show that they are not shot out with an initial velocity from the bottom of the cell, but that any departure from their normal paths is caused by the crowding. I conclude that to increase the pressure in a pneumatic cell simply causes more air to be liberated, the number of bubbles being increased thereby. There is lacking any force, save that of the buoyancy of the water, to give the bubbles anything resembling an initial velocity.

Petroleum in Czechoslovakia

Petroleum is found in two regions in Czechoslovakia, adjoining the Carpathians on the east in Slovakia and on the west in Moravia. The oil-fields of Slovakia are undoubtedly large, but have not been investigated sufficiently to permit of reliable estimates. In Slovakia drilling for petroleum is a State monopoly. The principal wells are found near Gbely, a small town of 3000 inhabitants, on the Kuty-Holie railway line, in the district of Nitra. This territory formerly was under Magyar domination. When it was taken over by the Czechoslovak Republic at the beginning of 1919, well No. 68 was about to be completed, while the drilling of three other wells was unfinished. At the end of 1919 well No. 82 was being bored and three other wells were being started, showing that considerable work had been done in 1919, notwithstanding the unfavorable conditions. The Gbely wells yield a heavy oil which is employed as a lubricant and has replaced the so-called vulcan lubricating oil formerly imported from Galicia. For the present the borings are confined to the Sarmatian strata. The wells are about 200 ft. apart, averaging about 835 ft. in depth. The Sarmatian oil is heavy, having a specific gravity of 0.930. The older Oligocene strata of the Tertiary formations have not been tapped as yet. A comparison with the Galician fields shows that those of Slovakia have not been explored sufficiently, for in Galicia the borings are only 130 ft. apart and the wells reach to a depth of as much as 4600 ft., at Tustanowiec even to 5250 ft. Preparations are now being made at Gbely for the boring of the first deep well. Two different methods of boring are employed at Gbely, the choice depending on circumstances: the so-called 'flushing' method, and the 'dry' method based on the system of Tank and Franzl. The flushing method possesses many advantages over the Canadian method, which is generally employed in Galicia, the chief one being the lower cost of equipment. It is said that the flushing method is much more economical, its effectiveness in comparison with the Canadian method being in a ratio of 6 to 1.

The Analysis of Magnesite

By W. C. RIDDELL

INTRODUCTION. Numerous inquiries have come to the Berkeley Experiment Station of the U. S. Bureau of Mines relative to the analysis of magnesite and magnesite products. Accordingly it seems desirable to publish a description of the method used at this laboratory in making the analyses required in the investigation of magnesite technology as conducted by the Bureau in co-operation with the Northwest Magnesite Co. Special attention has been given to the separation of calcium from magnesium.

A number of possible methods for the separation of calcium from magnesium have been reviewed by Kallauner and Preller.¹ These authors conclude that the oxalate method is the most satisfactory. They state that when the oxalate method is used on material containing approximately 50 parts of MgO to one part CaO, the error in the determination of CaO will be from 0.15 to 0.2% low. The experimental results in this laboratory indicate that with care this percentage of error may be reduced considerably. The article cited contains a full discussion of the various factors influencing the results.

The method of analysis outlined herewith is based on suggestions given by Brearley and Ibbotson,² for the analysis of basic material. The use of rosolic acid as an indicator is suggested by the work of Blum.³

This method has been in use in this laboratory for some time and the results have been checked by several operators. Some experimental data are appended showing the influence of various factors on the separation of calcium from magnesium.

METHOD OF ANALYSIS. For the analysis of crude magnesite a sample of one gramme is used; for the analysis of 'dead-burned' magnesite, 'ferro-magnesite', magnesite brick, and caustic magnesite a half-gramme sample is sufficient. The weighed sample in a 250-cc. pyrex beaker is moistened with cold water to avoid lumping, and 15 to 20 cc. of hydrochloric acid (sp. gr. 1.2) is added. Digest on the hot-plate and evaporate finally to dryness, continuing the heating until the silica is dehydrated. Heating in a drying-oven at 110° to 120°C. for half an hour is a convenient method of dehydrating the silica. To the residue add about 30 cc. of hydrochloric acid (1:1) and digest until all of the soluble salts are dissolved. Dilute with hot water to a volume of about 100 cc., filter the insoluble residue of impure silica, wash with cold water, and then with hot water until free from chlorides. The residue is ignited, weighed, and reported as 'insoluble'.

In order to determine the silica exactly the insoluble residue is treated in a platinum dish with hydrofluoric acid and a few drops of sulphuric acid and the silica-free residue is ignited and weighed. Care should be taken to heat the crucible to a temperature of at least 1000 C., as the residue generally contains magnesium sulphate which will not be decomposed at a temperature much below this. The residue from the volatilization of the silica is dissolved in hydrochloric acid, or fused with sodium hyposulphate if necessary, and added to the main filtrate.

To the filtrate from the insoluble residue add 7 to 8 gm. of ammonium chloride, dilute to about 200 cc., add macerated filter-paper and a few drops of rosolic acid as an indicator. Heat nearly to boiling, remove from the hot plate, and add ammonia in slight excess as indicated by the change in color of the indicator from yellow to pink. Filter immediately and wash with hot water, containing about 10 gm. of ammonium nitrate per litre, until only a faint opalescence appears on testing with silver nitrate. The washing of the hydroxides when precipitated in the presence of macerated filter-paper is readily accomplished. Ignite and weigh the precipitate, which consists principally of the oxides of aluminum, iron, and manganese.

Make the filtrate acid with hydrochloric acid, add 40 cc. of a saturated solution of ammonium oxalate, dilute to about 400 cc., heat nearly to boiling, remove from the hot plate, and add a slight excess of ammonia. Allow to stand for about one-half hour. Filter off the precipitate of calcium oxalate, wash two or three times with hot water, and then wash the precipitate back into the beaker, making sure to wash the filter-paper thoroughly.

Re-dissolve the precipitate with 5 cc. of hydrochloric acid, add about 5 gm. of ammonium chloride and 5 cc. of ammonium oxalate solution, dilute to about 200 cc., heat to boiling, neutralize the solution with ammonia, using rosolic acid as an indicator, and boil three to four minutes. Remove from the hot plate and allow to stand for about 15 minutes. Filter and wash the precipitate with hot water until free from soluble oxalates. Dissolve the precipitate in about 100 cc. of hot water to which 10 cc. of sulphuric acid (1:1) has been added, heat nearly to boiling, and titrate with 0.05 to 0.02-normal solution of potassium permanganate, which has been standardized with sodium oxalate from the Bureau of Standards.

Magnesium is determined in the combined filtrates from the calcium determination by diluting to a convenient volume, dividing into aliquot parts, and precipitating as the phosphate. Calculation of the magnesium oxide by difference is generally sufficiently accurate.

Iron is determined by the dichromite or permanganate

¹Kallauner, O., and Preller, I. 'Chem. Zeitung', No. 36 (1912), pp. 449 and 462.

²Brearley and Ibbotson, 'The Analysis of Steel-Works Materials', pp. 220 and 221.

³Blum, W. 'Determination of Aluminum as Oxide', Jour. Amer. Chem. Soc., No. 38 (1916), pp. 1282-97.

method, using a two-gramme sample, and is generally reported as ferric oxide.

Manganese is determined by the Volhard or bismuthate method.

Ignition loss is determined by heating at approximately 1000 C. for from 20 to 30 minutes.

EXPERIMENTAL DATA. The experiments recorded in Table I were made with a standard chloride solution prepared from pure calcium carbonate and magnesium chloride. The solution contained 0.009 gm. of magnesia and 0.0002 gm. of lime per cubic centimetre. For each experiment 50 cc. of this solution was used corresponding to 0.450 gm. magnesia and 0.010 gm. of lime. These quantities correspond to a one-gramme sample of magnesite or a half-gramme sample of calcined material.

The following conditions apply to all these experiments: volume used for first precipitation, 400 cc.; ammonium chloride added for first precipitation, 8 gm.; saturated solution of ammonium oxalate added 50 cc.

The following conditions apply to experiments No. 4, 5, and 6: volume used for second precipitation, 200 cc.; ammonium chloride added for second precipitation, 5 gm.; saturated solution of ammonium oxalate added, 5 cc.

No.	Time for first precipitation	Number of precipitations
1	Boiled 5 min.	1
2	Heated to boiling and allowed to stand 30 min.	1
3	Heated to boiling and allowed to stand 60 min.	1
4	Boiled 5 min.	2
5	Heated to boiling and allowed to stand 30 min.	2
6	Heated to boiling and allowed to stand 60 min.	2

It is evident from the first three experiments that with a single precipitation the results for lime are wrong. If the solution used for analysis is considered as representing a half-gramme sample of calcined magnesite, the corresponding lime content equals 2%. Calculating on this basis, experiments No. 4, 5, and 6 show 1.96, 1.94, and 1.80% lime respectively, an average error of -0.10%.

For the experiments recorded in Table II, a solution containing 0.003 gm. of magnesia and 0.0002 gm. of lime per cubic centimetre was used.

The following conditions apply to all experiments: volume used for precipitation, 400 cc.; ammonium chloride added, 8 gm.; saturate solution ammonium oxalate added, 40 cc.; number of precipitations, one.

No.	Standard solution used, cc.	Time for precipitation, min.	Deol normal potassium permanganate solution used, cc.	CaO found, gm.
1	50	30	3.5	0.0098
2	50	60	3.4	0.0094
3	50	boiled 5 min.	3.45	0.0097
4	50	30	3.3	0.0093
5	100	60	8.2	0.0220

It will be noted that in experiments No. 1 to 4 the average lime found was 0.0096 gm., as against a theoretical recovery of 0.0100 gm. In these experiments the 400 cc. of solution in which the precipitation was made contained magnesium chloride equivalent to 0.1500 gm.

magnesia. In experiment No. 5, where double the amount of magnesium was present, the result for lime on a single precipitation is distinctly high, being 0.0229 gm., as against a theoretical 0.0200 gm. These results, together with those in Table I, indicate the limiting concentration of magnesium in solution beyond which a double precipitation is necessary.

The results obtained by several different operators with the method described on three samples of magnesian material are given in Table III.

Sample Analyst	TABLE III

Graphite in Western Australia

Western Australia is fortunate in possessing one of the largest remaining known graphite deposits of the

TABLE I

No.	Time for first precipitation	Number of precipitations	0.1 N KMnO ₄ solution used, cc.	CaO found, gm.	Error, gm.
1	Boiled 5 min.	1	22.8	0.0784	+ 0.0084
2	Heated to boiling and allowed to stand 30 min.	1	35.0	0.0980	+ 0.0880
3	Heated to boiling and allowed to stand 60 min.	1	23.9	0.0669	+ 0.0569
4	Boiled 5 min.	2	3.5	0.0098	- 0.0002
5	Heated to boiling and allowed to stand 30 min.	2	3.45	0.0097	- 0.0003
6	Heated to boiling and allowed to stand 60 min.	2	3.2	0.0090	- 0.0010

world, and the Minister for Mines has announced that an English company is about to exploit it on a large scale. In the past this graphite has been considered worthless, but the extending uses, contracting supplies, and improved methods of treatment are making it profitable to mine lower-grade material. The chief uses are for pencils, the protection of iron surfaces (as in stove and other polishes), for making sundry refractory articles, such as crucibles, for lubricants, and for 'faïence' or glazing gunpowders, says 'Chemical Engineering and Mining Review'. Brodie's process is principally used for the purification of inferior graphites. In this, the graphite is treated with sulphuric acid and a little potassium chlorate, and oxidized to graphitic acid, C₁₁H₂O₅. The treated product is then washed, dried, and heated to redness, the graphitic acid is decomposed, and the graphite remains as a light, bulky powder, which can be separated from impurities by floating it away with water. When silica is present in great quantity, a little sodium fluoride is added after the potassium chlorate has been decomposed. Graphite of any desired purity can be formed in the electric furnace with the aid of silica, alumina, magnesia, or lime, which first form carbides and later distill into the cooler parts of the furnace. This process, however, is not likely to be used while natural deposits of graphite are available, on account of its comparatively high cost.

An Improved Wedge for Deflecting Diamond-Drills

By C. ERB WUENSCH

PURPOSE OF THE DEVICE. The scheme of deflecting diamond-drills by means of a wedge is not new; but the operation according to present practice is tedious. The position of the pilot wedge must be accurately surveyed for each deflection, and the wedge itself cannot be recovered; it serves for only one deflection. This consumes time and is expensive as compared with the method that can be used with the device to be described. It is possible to take a number of samples of a vein, or orebody that has been cut with a bore-hole, without a survey to determine the position of the wedge. By referring to

wedge consists essentially of two parts; the anchoring device (1) and the wedge itself (2). The anchoring device is simply a hollow cylindrical piece of soft wood with a corrugated surface. The hollow space (3) is to accommodate the lower part of the wedge (4) when the wedge is first placed in the hole. The upper end of the anchor has a thread as shown at (5). The purpose of this thread is to engage the metal cap (6) that contains the metal dog (7); while the purpose of this dog is to engage the steeply-pitching spiral grooves (8) on the shank (4), thus effecting the rotation of the wedge (2) when it is drawn up by the recovery wedge (18).

FIG. 1. STEREOGRAPH OF VEIN BEING DRILLED

the accompanying stereographic sketch, Fig. 1, the purpose of the device can be readily comprehended.

A deep bore-hole (1) has penetrated a vein. The sample recovered may be representative or it may not be. In order to obviate this uncertainty the deflector is placed in the hole, at random; the rods and bit are then reinserted and the first deflected hole (2) is drilled; the rods are withdrawn and the bit replaced by a recovery-tool which engages the wedge. The wedge is turned automatically through any desired angle (90° in this sketch), when the recovery wedge may be released, leaving the deflecting wedge in the new position. Drilling is again resumed, and this time the next hole (3) is drilled. This operation is repeated until the fifth hole is drilled, after which the recovery wedge is used to withdraw the multiple deflector from the hole. Nothing is lost but the wooden anchor, which is inexpensive. Thus we have five cores, accurately spaced, from which a reliable sample can be obtained.

DESCRIPTION OF THE MECHANISM. As shown in the accompanying sketch (Fig. 2) the multiple-deflecting

The grooves (8) on the shank (4) pitch steeply and are of uniform depth at all points except at such points as 9, 10, 11, and 12, which are at 90° from each other as shown in the sketch, and are for the purpose of effecting the release of the recovery wedge. It will be noticed that the inner rod is notched at the points 14, 15, 16, and 17. These notches are engaged by the dog (7) when the wedge (2) is rotated, because at points 9, 10, 11, and 12 the grooves (8) have holes cut in them to permit the dog (7) to extend deep enough.

When the dog (7) is engaging the notch (15), as shown, the wedge (2) is moving upward, the anchor (1) is stationary, and hence the inner rod (13) is pulled downward. When this happens, the catch (19) (see section *A A'*) is pushed downward to the position 19 A by means of the wedge (24), which exerts a pressure on the base of 19; 24 moves downward to the position 24 A, so that the dog (20), which is engaged in the notch (32) of the recovery wedge is permitted to move upward and disappear within the wedge (2), as shown at 20 A, thereby releasing the recovery wedge.

The dog (20) is mounted in a small and strong metal block (21) (see section *D D'*) which has a slot (22) sufficiently large to accommodate the dog (20) when it disappears as shown at 20 A. The disappearance of the dog (20) is effected as follows: when the catch (19) permits the block (21) to move upward in its slot (22) the dog disappears because of the pressure at the point 23 of the deflecting wedge.

As soon as the recovery wedge (18) is released, the block (21) is pushed downward by virtue of the pressure

applied by the spring (25), and the dog (20) as soon as it passes point 23 again appears extended because of the pressure exerted by the spring (26); as soon as the dog (and, of course, also the block) is in this position, the catch (19) again returns to its normal position as shown in section A-A'. It will be noticed that at the bottom of the shank (4) of the deflecting wedge, there is a shoulder (27) which has a spring (28) pressing against it. This pushes the inner rod (13) so that its upper end (24) simultaneously assumes its normal position as do the dog and the catch.

In order to emphasize the positive and automatic action of this releasing arrangement, I wish to mention a few details. The dog (7) releases the same catch (19) instantly, but before the recovery wedge (18) has been released by the dog (20) the whole wedge (2) has moved upward the distance that x in section A-A' the block

wedge to rotate with the deflecting wedge (2) as it is being revolved into a new position and thus prevent the notch (32) from slipping off the dog (20). Also notice the threads (33) on the end of the recovery-wedge, that permit its being attached to the end of the rods when it replaces the bit of the diamond-drill.

When the wedge and anchor are lowered into the hole, it is evident that it will be necessary to have some means of holding them together. This is done by screwing a small metal strip along the side of the wedge and anchor. This metal should be barely strong enough to hold the two together so that no difficulty will be experienced in sheering it when the wedge is rotated.

Mention has been made of the fact that the anchor is made of soft wood with a corrugated surface. The purpose of the corrugations is to permit the cement to make the anchor more secure; the soft wood will also assist in

FIG. 2. DETAILS OF DEFLECTING AND RECOVERY WEDGES

(21) moves through before the dog (20) entirely disappears. This means that the other dog (7) no longer engages the notch (15), but is itself in its normal position, that is, engaging the groove (8). Another point is the manner in which the dog (7) prevents the wedge (2) from moving backward (downward) after it has once been pulled forward and rotated. The dog (7) is mounted by a pivot at point 29, which permits the dog to move out when the wedge is drawn upward, but, as soon as the wedge attempts to settle downward, the point of the wedge (7) digs into the bottom of the groove (8) and thus prevents it changing its position.

Referring to sections B-B' and C-C', it will be noticed that, when the recovery-wedge (18) is inserted in the hole, it is impossible for it to engage the dog (20), unless the wedge (18) is in the proper position so that it can pass along the face of the deflecting wedge (30), and assume the position as shown by the dotted line (31) after which the notch (32) will easily engage the dog (20).

Note the construction of the upper end of the recovery-wedge. The purpose of this construction is to permit the

this because it will swell when wetted. While the device has never yet been tried, it is mechanically plausible and I hope to make and use a wedge constructed according to this plan in some prospecting and development work that I expect to do within a few months.

THE petroleum-refinery capacity of the United States is considerably overbuilt, according to figures of the Bureau of Mines. At present refineries have a total rated capacity over 50% in excess of the refinable oil supplies, which is likely to be near 80% when the refineries now under construction are completed. The oil-runs to the refineries of the United States for the year 1919 were 361,520,153 bbl. of crude oil, or 990,466 bbl. per day. In December 1919, the refineries in operation had a daily capacity of 1,356,355 bbl. per day, whereas, the daily run of crude oil to the stills was 1,046,052 bbl., indicating that they are running at only 73% of their rated capacity. Refineries of an additional 174,210 bbl. capacity per day were idle, while refineries totaling a capacity of 263,000 bbl. daily are reported to be under construction.

Federated American Engineering Societies

At a meeting attended by representatives of 67 national, state, regional, and local engineering and technical societies in Washington on June 3, the following resolution was adopted:

Resolved, That it is the sense of this conference that an organization be created to further the public welfare where technical knowledge and engineering experience are involved and to consider and act upon matters of common concern to the engineering and allied technical professions, and

Resolved, That it is the sense of the conference that the proper organization should be an organization of societies and affiliations and not of individuals.

The American Association of Engineers opposed the resolution during the discussion, but voted in the affirmative when it became apparent that the prevailing sentiment was strongly favorable. After protracted debate a constitution was agreed upon, 49 organizations casting their votes for adoption, the others being undecided as to their course. The constitution follows:

ART. I. NAME

THE NAME OF THIS ORGANIZATION SHALL BE FEDERATED
AMERICAN ENGINEERING SOCIETIES

ART. II. OBJECT

Service to others is the expression of the highest motive to which men can respond, and duty to contribute to the public welfare demands the best efforts that men can put forth, therefore, it shall be the object of this organization to further the interests of the public through the use of technical knowledge and engineering experience, and to consider and act upon matters common to the engineering and allied technical professions.

ART. III. MEMBERSHIP

Sec. 1. *Scope*: The membership shall consist of national, local, state, or regional engineering and allied technical organizations and affiliations, classified as follows:

(1) National engineering and allied technical organizations.

(2) Local, state, or regional engineering or allied technical organizations other than local associations, sections, branches, or chapters of national organizations.

(3) Affiliations consisting of any one, or a combination, of the following constituents:

(a) Local sections or associations of members of national organizations included under (1).

(b) Local engineering or allied technical societies or clubs, not of national scope.

(c) Local engineers and members of allied technical professions and their associates.

Sec. 2. *Qualifications*: The qualifications for membership shall be as provided in the by-laws.

Sec. 3. *Application for Membership*: Application for membership shall be made in the form and manner prescribed in the by-laws.

Sec. 4. *Termination of Membership*: The membership of any constituent organization may be terminated by it or by the Council in the manner provided in the by-laws.

ART. IV. MANAGEMENT

AMERICAN ENGINEERING COUNCIL

Sec. 1. The management of this organization shall be vested in a body to be known as the "American Engineering Council", and its executive board.

Sec. 2. *Functions*: The American Engineering Council shall consist of representatives of member-societies selected as hereinafter provided. This Council shall co-ordinate the activities of state councils and of local affiliations whenever these activities are of national or general importance or may affect the general interests of engineers.

Sec. 3. *Representation*: Each national, local, state, or regional organization or affiliation shall be entitled to one representative on the Council for a membership of from 100 to 1000 inclusive, and one additional representative for every additional 1000 members or major fraction thereof; provided that in the determination of the representation of local, state, or regional organizations or affiliations no count shall be taken of any organization which is represented individually or through another local, state, or regional organization or affiliation; and, provided further, that no organization shall have more than 20 representatives on the Council.

Sec. 4. *Selection of Representatives*: Representatives on the Council shall be selected as stipulated in the by-laws.

Sec. 5. *Meetings*: The Council shall hold an annual meeting. Other meetings may be called by the executive board and shall be called by it upon the written request of 25 representatives on the Council.

Sec. 6. *Officers*: The elected officers of the Council shall consist of a president, to hold office for two years, and who shall be ineligible to re-election, four vice-presidents, to hold office for two years, two to be elected every year, and a treasurer, to hold office for one year. These officers shall be elected by a letter ballot of the representatives on the Council as provided in the by-laws. There shall be an executive officer who shall also be secretary appointed by and holding office during the pleasure of the executive board. He shall not be a member of the executive board but may be a representative on the Council.

EXECUTIVE BOARD

Sec. 7. *Functions*: There shall be an executive board of 30 members of the Council constituted as hereinafter provided and charged with conducting the business of the organization under the direction of the Council.

Sec. 8. *Membership*: The executive board shall consist of thirty members, of whom six shall be the officers elected by the Council and twenty-four shall be selected, a part by the national societies, and the remainder by the local, state, or regional organizations or affiliations according to districts, as provided in the by-laws; provided, that the number of representatives of the national societies shall bear as nearly as may be the same ratio to the number of representatives of local, state, or regional organizations and affiliations as the representation of the national societies bears to the representation of the local, state, or regional organizations or affiliations.

Sec. 9. *Electoral Districts*: For the purpose of facilitating the selection of the district members on the execu-

Sec. 1. The Council shall divide the country into districts as provided in the by-laws based upon an equitable basis, having regard to both its membership and area.

Sec. 10. *Officers:* The president and secretary of the American Engineering Council shall be respectively the president and the secretary of the executive board. There shall be two vice-chairmen elected by the board for its members.

ART. V. UNEXPIRED TERMS

Vacancies in the offices of the president, the vice-presidents, the treasurer, and in the executive board and among the representatives on the Council, shall be filled as soon as feasible, by the agencies originally selecting the incumbents. Officers and delegates thus chosen shall serve for the unexpired terms.

ART. VI. FUNDS

Sec. 1. Funds for the use of the organization shall be contributed as follows:

(a) Each national society represented on the American Engineering Council shall contribute annually one dollar and fifty cents (\$1.50) per member.

(b) Each local, state, or regional organization or affiliation represented on the Council shall contribute annually one dollar (\$1) per member.

No portion of such funds shall be applied to the use of local affiliations or state councils.

Sec. 2. The American Engineering Council may receive and administer gifts, bequests, or other contributions for carrying out the purposes of the organization.

ART. VII. LOCAL AFFILIATIONS

Sec. 1. *Object:* The American Engineering Council shall encourage the formation of local affiliations, to consider matters of local public welfare with which the engineering and allied technical professions are concerned, as well as other matters of common interest to these professions, in order that there may be united action and that suggestions and advice may be offered to the Council.

Sec. 2. *Constitution:* Each local affiliation desiring membership in this organization shall submit its constitution and by-laws and all subsequent amendments thereto to the executive board of the Council for approval of such portion thereof as may affect its eligibility, or its relation to the work of the Council.

ART. VIII. STATE COUNCILS

Sec. 1. *Object:* State councils, consisting of representatives of local affiliations within the state or otherwise representative of the majority of engineers and members of allied technical professions in the state, if members of this organization shall consider state matters of public welfare with which the engineering and allied technical professions are concerned, as well as other matters of common interest to these professions, in order that there may be united action in state affairs.

Sec. 2. *Constitution:* Each state council desiring membership in this organization shall submit its constitution and by-laws and all subsequent modifications thereto to the executive board of the Council for approval of such portion thereof as may affect its eligibility, or its relation to the work of the Council.

ART. IX. DELIMITATION OF AUTHORITY

Local societies, affiliations, state councils, and the American Engineering Council, shall deal with local, state, and national matters respectively, and they shall

be autonomous with respect thereto. It shall, however, be the duty of the American Engineering Council to interest itself in the activities of local affiliations and state councils if such activities are of national scope, or affect the general interest of the engineering and allied technical professions; provided, that nothing herein stated shall be construed as preventing the discussion by any local affiliation or state council or by the American Engineering Council of any matters of interest to engineers and members of allied technical professions, or action by the said Council on local or state matters where no local affiliation or state council exists.

ART. X. AMENDMENTS

Sec. 1. An amendment to this constitution may be proposed by the executive board.

Sec. 2. An amendment may be proposed in writing, by at least 25 representatives on the American Engineering Council; such amendment shall be considered first by the executive board, which may approve, disapprove, or formulate a modified or alternative amendment, report of which action shall accompany the original proposal to this organization.

Sec. 3. Any amendment proposed as provided in Sec. 1 and 2 shall be considered at a meeting of the American Engineering Council and shall be submitted to its members at least 90 days in advance of such meeting. At this meeting, provided a majority of the representatives are present, the amendment may be rejected, or ordered submitted to the members of the Council for letter ballot within 30 days thereafter, with such modifications as may be adopted by a majority of those present. The amendment shall fail of adoption if one-third of the votes cast are in the negative.

THE MOUNT MORGAN MINE produces practically all the gold from Queensland. The mine last year had an output of gold worth £381,351, besides copper to the value of £506,255. Development in this mine during the year consisted of 256 ft. of sinking, which was directed mostly toward facilitating the mining of the various sections. The quantity of ore raised and treated was 281,900 tons, and of this, 118,800 tons was sent directly to the smelters, the remainder (163,100 tons) passing through the concentrating plant. The total treated was 69,051 tons less than in the preceding year, the reduction, principally in concentrating ore, being attributable, not to any decreased capacity of the mine or plant, but to unusually long holidays at Easter and to a complete closing down for two or three weeks in June, owing to a strike of seamen on the Australian coast. The stopes are filled, mostly with concentrator tailing, as the ore is extracted. Another sintering unit has been completed, and as a consequence the rotary furnace and pot-sintering plants were discontinued after the Easter vacation. A flue-dust cooling and handling-plant has also been added to the equipment; the concentrating plant has been improved by the addition of two Dorr thickeners and two tube-mills, each of the latter requiring 80 horsepower, while two roasting-stalls, including flues, with the necessary crushing-plant, have been erected at the West Works. The company has extracted from the more shallow levels of the orebody some high-grade silicious gold ore, but the quantity of this ore is limited.

REVIEW OF MINING

FROM OUR OWN CORRESPONDENTS IN THE FIELD

ARIZONA

NORTH TIGRE LEASING CO. STARTS NEW MILL.

BISBEE.—The Goras Leasing Co., which has been operating for approximately three years, is now shipping 20 cars per month, averaging 7 to 8% copper. At a recent meeting a dividend of 10c. per share, payable June 20, was declared. It is understood that this is the first of regular monthly dividends of 10c. which the company expects to pay in the future. The Calumet & Arizona Mining Co. is engaged in sinking a ventilating shaft at its Briggs mine. This shaft connects with the 770-ft. level and will furnish a permanent outlet for smoke and gases from the large sulphide orebody, which has recently given some trouble.

It is said that the cost to Cochise county for the prosecution and acquittal of H. E. Wooten, first of 209 defendants in the Bisbee deportation cases, amounted to \$50,394. The trial of the 'blanket cases' has been postponed until fall.

The 50-ton mill, which has been in process of erection at the North Tigre Leasing Co., is now complete and in operation. The company expects to produce seven tons of concentrate daily, assaying not less than 350 oz. silver. More than 40,000 tons of silver ore, said to assay 35 oz., has been blocked out on the property. At the Flux property at Patagonia the new drift on the 260-ft. level that will explore the ground under the big carbonate ore-deposit has been driven 150 ft. through solid limestone to a point where further sulphide deposits should be penetrated. About four feet per shift is being made in the drift and the work will be pushed to thoroughly develop the 260-ft. level. Between 90 and 100 cars per month, averaging from \$20 to \$50 per ton, of silver-lead ore is being shipped by Tombstone lessees to the smelter at El Paso.

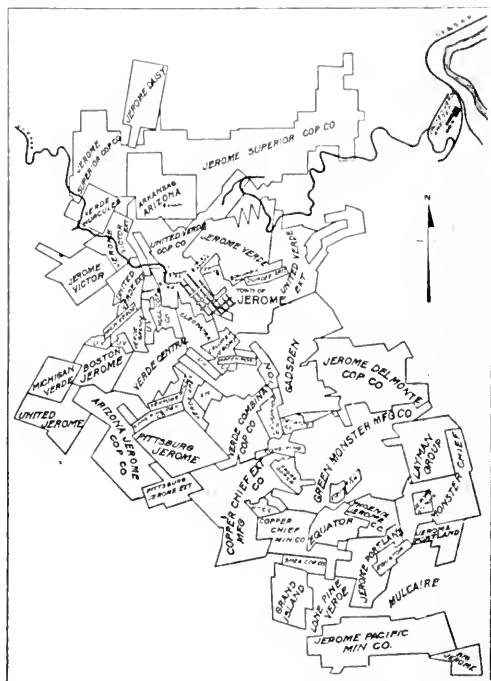

JEROME.—The United Verde Extension Mining Co. has declared the usual dividend of 50c. per share payable on August 1, to stockholders of record as of July 8. The Jerome Superior has decided to discontinue the use of oil-burning engines and electrify the plant throughout. This company has increased its directorate from five to nine members, one of the new directors being E. C. Joannes, head of the Joannes Tea Co. Work on the carbonate reef at the Dundee mine is said to be progressing steadily and satisfactorily. The process of treating this ore which has been developed at the Humboldt smelter is proving quite satisfactory and from 85 to 90% of the valuable metal is being recovered. It is understood

that a 100-ton plant is to be built immediately at Humboldt and that it is more than possible that a similar plant will be built on the Dundee.

CALIFORNIA

UNWATERING OF JACKSON MINES IS PROGRESSING SLOWLY.

AMADOR COUNTY.—But little headway is being made in unwatering the Kennedy and Argonaut mines near Jackson, both having been flooded to the Argonaut's

PROPERTY MAP OF JEROME DISTRICT

3500-ft. level last April in order to extinguish a fire which had been burning a year and was beyond control. To date all the hoisting of water has been done by the Argonaut alone. In the past five weeks the water-level has been lowered only 50 ft. Three air-lift pumps are ready for installation. The Kennedy company operates a steam-hoist, but so far it has been unable to secure

fuel oil. The two mines are connected at different points down to the 4200-ft. level and to some it appears that the Kennedy people are using the situation as a club, considering the fact that the fire started in the Argonaut mine and finally reached the Kennedy workings. The latter company has levied assessment No. 6 of 15c. per share delinquent on June 21.

The work of unwatering the Fremont mine is progressing steadily. This property comprises the Fremont, Gover, North Gover, and Loyal lode claims, covering 4200 ft. on the Mother Lode. They have been worked through shafts on the Gover and the Fremont claims. Excessive costs due to war conditions caused the owners to discontinue mining low-grade ore about two years ago, since which time some of the surface machinery has been disposed of and the mine allowed to fill. Edwin Higgins is directing the work, and during the past two months the surface plant has been overhauled, electric motors and other modern machinery installed, and a good start made toward emptying the mine of water. In addition to better-grade ore that increased depth may reveal, a return to normal conditions as to labor and supply costs or government aid in the way of a gold bonus may assist the operation of the property. Alex Ross, formerly mine-forman at the Kennedy, is superintendent.

Improvements to the surface-plant at the Central Eureka mine are under way. A new compressor, air-receiver, and boiler are now being installed; wooden mortar-blocks in the mill have been replaced with concrete, resulting in the successful handling of increased tonnage, and the shaft is now being sunk for a new level 150 ft. below 3700 ft., which is now the lowest point; 30 stamps of the 40-stamp mill have been operated steadily for many months, and probably additional stamps will be dropped when ore is obtainable from the new level. Sinking to the depth desired will be completed at present rate of progress by the middle of next month. After many years of assessment, stockholders have been receiving regular three-cent dividends since December 1919. Albion S. Howe is the superintendent of the mine, which adjoins the Old Eureka property on the south.

The shaft-contract for increasing the depth of the Old Eureka mine from 3050 to 3550 ft. was completed this week, after a long tedious struggle with heavy ground. The swelling ground caused the repeated crushing of 16 by 16-in. timbers. Four or five times timbers have had to be eased off; even the 18 by 18-in. material which was finally resorted to failed in many places to hold the ground. Similar difficulty was met in the previous sinking operations, but that part of the shaft appears now to have settled into satisfactory shape. A station will be cut and levels run to prospect the mine at this depth. Several promising veins have been cut during the course of re-opening this old mine, but the company appears to be devoting most of its energies toward attaining depth before attempting extensive lateral development. T. C. Gorrie is superintendent.

YREKA.—J. C. Hubbard, representing Seattle and Yakima, Washington, people, has been prospecting in

the Yreka district the past four years for gold properties. In 1919 he purchased the Spring Gulch property, then the Wacker mine, and later the Osgood, the Mono, and other adjoining mines and prospects, which now aggregate 500 acres. The Osgood is equipped with a five-stamp mill which is now working on the dump. He proposes to install a 50-ton Lane crusher to operate on the 30,000-ton dump on the Osgood, which averages \$7 per ton of free gold. These several properties have been operating the past 30 years and have produced in a crude way over \$100,000. The whole property has been carefully surveyed and platted by the new owners, who plan to operate the mines systematically.

COLORADO

EXPLORATION TUNNELS BEING DRIVEN AT ASPEN.

ASPEN.—The Park tunnel has been driven 2300 ft. with 800 ft. remaining for the projected connection with the Last Dollar incline, sunk on the Justice fault, in the Tourtelotte Park section. The heading is now in quartzite, believed to be intrusive. The Hope tunnel is following the Hope fault and it is expected that ground favorable to the deposition of ore will shortly be entered. The contact has been the chief source of ore nearer Aspen. The lime now contains some silver. Both tunnels are operated by the Hope M. M. & L. Co. In the Jenny Lind tunnel a raise is going up in what is believed to be the Silver contact between Blue lime and Weber shale. The ore broken is being saved for shipment. The shoot at the tunnel level is 70 ft. long.

BRECKENRIDGE.—Operations have been resumed in the Sunnyside tunnel entering Gold hill, in the 10-Mile Consolidated district, by E. D. Burke of Cripple Creek. A lead-carbonate ore assaying as high as \$110 per ton is being mined from a four-inch streak and the remaining matter in the four-foot vein averages \$27 per ton. The ore contains 26% lead and as high as 32 oz. silver and some gold.

Stilwell Connor operating the Pearl property, in the Robinson district, is mining a good grade of silver ore through a tunnel. He will soon start shipments to the A. V. smelter at Leadville. The Pearl is controlled by the estate of the late C. J. Moore.

SILVERTON.—The Queen City property in Ohio gulch in the Gladstone district, a former shipper of high-grade silver-lead ore, has been leased after years of inactivity and is in operation. The United States Mines Corporation owning the Copper Belle in Whitehead gulch has let a contract for extending its tunnel to local miners. The object is to cross-cut the Copper Belle vein that produced rich ore in workings nearer surface. The Gold King Extension mill is running steadily and from one to three cars of concentrate is shipped to the smelter daily.

GEORGETOWN.—Roads are rapidly being re-opened and mining activity is increasing accordingly. Supplies have been sent up to the Waldorf, where work has been resumed and the Jeffery property, in Grizzly gulch, is again active. At the Denbigh men are repairing the pipe-line

and water-power will be substituted for steam. The working force will be increased when power is available.

The new tramway at the St. George started operating this week and ore is now moving. A compressor and other equipment is being installed in preparation for rapid development during the summer season. A consignment of two to three-ounce gold ore was shipped last week from the Ramsdell mine on Lincoln mountain, by the owner, John A. Heim of Empire.

MAYDAY.—Milton Deluche, operating the Esmeralda, situated on the south fork of Lightner creek, is mining ore from a vertical lime contact; it assays 19 oz. silver per ton. Tom Welborn and Joe Clark, lessees on the Idaho dump, are shipping ore said to assay $2\frac{1}{2}$ oz. gold per ton. Fred Brandiger is loading a car of high-grade

Physically the mine is in prime condition. There is no difficulty except the shortage of miners. Baltic produced 15,000 tons last month. In April Baltic produced 17,400 and a year ago was producing 20,000 tons monthly. Tri-mountain produced in May, this year, 8,900 tons of rock, compared with 11,700 in April and 16,000 a year ago. These mines are having the additional problem of a continual drain of employees to the manufacturing centres and the local farms.

Seneca's total output in May was 5611 tons which averaged over 30 lb. In April Seneca produced 3569 tons. Seneca's production for June will be well over 7000 tons if the present rate is maintained.

The one large piece of construction work to be undertaken in the Lake Superior district this year is the re-

THE KENNEDY MINE, AMADOR COUNTY, CALIFORNIA

ore from his lease on the Idaho. The Jumbo Mining Co. is shipping from a lease on the Jumbo. Henry Houser has started work at his property west of the La Plata. The cross-cut at the Little La Plata, which is in 170 ft., is being pushed, but as yet no vein has been found.

MICHIGAN

RE-TREATING PLANT FOR TAMARACK SANDS.

HOUGHTON.—While the copper content is higher than at any time in recent years, and while the amount of mass and barrel copper is larger than it has been for a long period, the production of copper 'roek' from the three mines of the Copper Range company, the Champion, Tri-mountain, and Baltic, has reached the lowest point in recent years. Champion, the richest mine in the district, now turning out a grade of rock which is averaging 45 lb. to the ton, produced 22,000 tons last month. A year ago Champion was mining 38,000 and 40,000 tons per month. In April, this year, Champion produced 25,400 tons.

treating plant to be built for the Tamarack sands on the shores of Torch lake. This work will be undertaken by the Calumet & Hecla corporation. It will involve an expenditure of at least two millions of dollars. The purpose of the plant will be to treat the old Tamarack conglomerate sands. The plant will be an exact duplicate of the Calumet & Hecla plant at Lake Linden where the Calumet conglomerate sand now is being treated. This Lake Linden treater demonstrated the metallurgical practicability of working this old tailing. Today this mill is the one surely profitable operating 'mine' in the copper district. Its costs are down to six cents. Little labor is required. The assays are true to form in the returns secured. There is at least 50,000,000 tons of sand still in the lake to be treated. Calumet & Hecla purchased the Tamarack outright seven years ago, shortly after the attempt of the Calumet & Hecla interests to consolidate many of the copper-producing corporations in which the older company had a stock interest. The Tamarack mine originally was established because Michigan mining laws

geologic lateral boundaries, not the apex rule. The Tamarack bought property on the lateral extension of the Calumet conglomerate lode, and went down through dead ground for a mile before encountering the formation. It operated independently for 30 years, with varying success. The milling results were about the same as the results of the Calumet & Hecla and the tailing losses were large; the material piling up on the lake shore totaled 30,000,000 tons. Complete assays have been made and the tests have been on a line with those made of the same lode on the Calumet property. The result is the determination to treat this sand by exactly the same method now in use on the Calumet sand.

The coal situation is becoming more and more embarrassing for the copper mines. Some properties will be compelled to suspend operations within 30 days unless there is a change. Calumet & Hecla interests have enough to run 60 days but no longer. The copper mines are in a quandary as to the future. According to present figures their coal will cost them \$12 per ton, delivered, if they make contracts at present prices. Such prices are prohibitive for every mine in the district unless copper sells at 30¢, instead of at 20. The coal bill for the copper mines of Michigan will be higher than \$14,000,000 at the present price. Copper Range mines bought some coal from the recently suspended Winona and picked up some from the Beacon Hill, enough for a couple of weeks. They considered themselves fortunate to get it. Mohawk is experimenting with steel scrapers using four of them successfully in flat stopes where gravity helps out the trammers. Mohawk is securing more mass than ever before in its history from the regular vein material, not from the fissure vein.

MONTANA

NEW DISCOVERY BY BUTTE-JARDINE COMPANY.

HELENA.—The Vera Cruz company has uncovered a rich silver vein on its 150-ft. level. M. J. McEvans reports a promising outlook for the property.

NEHAUT.—Development at the Moulton, when the lode is re-opened, will be confined to thorough lateral exploration by the extension of levels. This development work will continue for several months or until the extent of the orebody is determined. The shaft is down 600 ft. A winze has been sunk 100 ft. below the 600-ft. level. The mill before the close-down was operating on an old dump and on ore from lessees. Drifting on the 300-ft. level of the Hartley mine has reached points 40 ft. to the north and 50 ft. to the south. Samples from these drifts assay 80 to 100 oz. silver per ton. The north drift on the 200 ft. level also shows considerable ore of a high grade.

SALTUSE.—Work has been resumed at the Lawrence mine with a crew of 12 men. A wagon-road has been opened to the property. A 200-ft. tunnel is being driven west to open up the ore bodies. H. M. Lancaster is engineer in charge.

DEER LODGE.—The Butte-Jardine Mining & Milling Co. reports a find of rich silver ore on the 600 ft. level of

its Champion mine. The ore assays more than 600 oz. silver and nearly 2 oz. gold per ton. Further work shows ore to come from a vein and not from a pocket. The ore will be hauled by team a distance of six miles, where it will be loaded for shipment to the smelter. Fifteen men are employed at the property.

NEVADA

ROUND MOUNTAIN COMPANY WILL MAKE GOOD PROFIT FROM PLACER OPERATIONS.

ROUND MOUNTAIN.—It is predicted that the final clean-up of the sluices of the Round Mountain Mining Co. will show the best results in the history of the company. It is expected that not less than 100,000 yards of gravel of an average value of \$1 per yard will be washed during the present season, as indications are that there will be ample water to continue work until late in September. The placer field is estimated to contain 2,000,000 yards of gravel averaging \$1, the bed-rock in places being at a depth of 75 ft. Two giants use water held by dams in Jett and Shoshone canyons. The placer was deposited by the erosion of the quartz veins of Round mountain and the field extends around the mountain and westward into Smoky valley.

RAILROAD SPRINGS.—The Silver Coin Mining Co., owning nine claims four miles west of the Allied, has been financed in San Francisco and the East and work will be started on July 1. A small hoist and pump have been bought. The first work will be in extending drifts from a 75-ft. shaft in which ore from 6 in. to 3 ft. wide gives high assays in silver.

GOLD MOUNTAIN.—The tunnel of the Washington Gold Quartz will reach the objective, a point under a 20-ft. shaft, in an additional 40 ft. Good ore was found in this shaft and the tunnel will cut the vein at a depth of 140 ft. The company is well financed and if ore is found it is planned to do a large amount of work.

MONTEZUMA.—The shaft of the Montezuma Silver Mines Corporation is 375 ft. deep and sinking is being continued. The finding of rich ore by this company several months ago at a depth of 250 ft. caused a rush into the district, but the ore was in a small lense and little work was necessary to prove the find of no value. Sinking was then resumed and this has resulted only in the opening of unimportant seams of rich ore.

DIVIDE.—The Belcher company is to be reorganized on an assessable basis. A statement issued in announcing the reorganization gives the cash in the treasury on June 1 as \$3172. The operating expenses from January 1, 1919, to June 1, 1920, were \$44,545, of which \$25,560 was for labor and \$18,985 was for supplies. The cost of shaft-sinking is given as \$39.61 per foot and of drifting, \$12.31.

GOLDFIELD.—The Grandma continues cross-cutting from a winze from the 815-ft. level and low assays are being secured. If ore is not found by July 1 preparations will be started to resume sinking the shaft. A 100-ft. drift is now used as a snop and when sinking is resumed water from below the 815-ft. level will be raised to this

sump and lifted to the surface by a pump on the level. The Great Bend has driven 65 of a necessary 100 ft. to drift around bad ground on the 375-ft. level and when the work is completed drifting from a raise from this level will be continued. A lease has been let west of the shaft, where the company has done no work except on the 400-ft. level. The lessees are prospecting on the surface for an ore-shoot and if they succeed in finding one the company shaft will be used in further work. Lessees on the 650-ft. level of the Jumbo Extension have shipped a carload of ore from which returns have not been received. They are now cross-cutting north-west from the main shaft to cut the downward extension of a shoot from which ore was shipped several years ago. It was the stopping of ore in this territory north-west of the main shaft

erected it will give a total of 18 stamps of different types and weights.

PICOP.—The shaft of the Prince Consolidated is 640 ft. deep and it is being sunk three feet daily. At the 600 ft. point a cross cut has been started to a 'gold' vein 200 ft. distant. The next lateral work will be at about 800 ft., where the diamond drill cut 10 ft. of ore assaying 30 oz. silver and \$4 in gold. Nearly 7000 tons of ore was shipped last year from the upper levels. The object of deepening the shaft is the exploration of beds of quartzite under the lime-shale from which the early production was made. Nearly 1,000,000 tons of ore has been taken from the upper formation.

VIRGINIA CITY.—The all-steel New Zealand-type dredge of the Gold Canyon Dredging Co. has been launched in

THE BADGER STATE MINE OF THE ANACONDA COMPANY AT BUTTE

and near the line of the Clermont mine of the Consolidated that led to the Booth apex suit. The Development has started the mill, using 10 stamps. The first ore is coming from the Red Top mine of the company. The tunnel of the Five to One, in the far southern part of the district, is over 400 ft. long. Richer pannings than at any previous point are being secured, but there is no indication that the tunnel will cut a vein.

TYLE CANYON.—The shaft of the Silver Hills, operating the Ingalls under option, is 45 ft. below the 100-ft. level, where sinking was started by the Silver Hills. The shaft is now in soft line and there is exposed in it a three-foot width of ore assaying 120 oz. silver and \$20 in gold. The present depth has been reached with hand-drills, but a compressor is being put in place. The five-stamp mill is treating ore from above the 100-ft. level and additional stamps are being purchased. The mill equipment is being bought second-hand at a number of places and when it is

the Gold Creek placer field, near Silver City. The dredge dumps buckets of nine cubic feet at a rate of 20 per minute. It weighs 900 tons and is 108 ft. long and 52 ft. wide. The dredge is single-lift with stacker and it will work to a depth of 40 ft. The sand is delivered to a trommel and the fine goes over tables of a total area of 3000 sq. ft. Electric power will be furnished by the Truckee General Electric Co. and the water will come from the pipe-line of the Virginia and Gold Hill Water Co. The field as prospected contains 200 acres. The Gold Canyon Dredging Co. is one of several companies promoted by Bulkeley Wells for operations in the Virginia City district.

MESA.—Commercial ore has been found in cross-cut 701 on the seventh level, 150 ft. below the sixth level of the Simon Silver-Lead property. This is the first verification of the belief expressed by Walter Harvey Wood, in his report on the property dated December 5, 1919,

ore bodies developed on the sixth level would be found to extend deeper. Pumps on the seventh level are carrying the increased flow of water without difficulty. The cross cut on the sixth level beyond the west fault is following a high-grade streak of silver ore.

High-grade ore has been found in the south-west cross-cut on the 350-ft. level of the Simon Contact property. A cross cut is being driven to cut the Mammoth vein that enters the Contact property from the Simon Silver-Lead ground, adjoining on the south. It has already been opened on the surface by trenches for a distance of 450 ft. The cross-cut being driven from the 100-ft. level of the Fagan Consolidated property to cut the fissure 60 ft. west of the shaft has entered mineralized ground after passing through 42 ft. of barren limestone. The shaft is being sunk an additional 200 ft. Nineteen sacks of high-grade silver ore were shipped by express from the C and A property to the Selby smelter. The shipment was insured for \$1 per pound. Assays from various sacks ranged from 920 to 9448 oz. per ton.

UTAH

WORK ON NEW UTAH CONSOLIDATED CONCENTRATOR TO START.

BINGHAM.—Construction of a flotation-plant at an approximate cost of \$500,000 with a capacity of 1000 tons per day for the purpose of handling the low-grade ores of the Highland Boy mine, will begin immediately. Officials of the Utah Consolidated company and of the General Engineering Co. visited the site near the International smelter at Tooele where they say an ample water-supply for the plant is available. The ore will be transported from the mine at Bingham to the new mill, a distance of four miles, by the overhead tramway which is in use at the present time for handling straight-smelting lead and copper ores. Last year the company leased a small mill and began a series of exhaustive tests. Recent development work in the mine is opening up copper milling-ore on the lowest levels in the Highland Boy and Yampa limestones.

Development work of an important nature is being pushed at the Montana-Bingham mine, according to Thomas P. Billings, consulting engineer. While shipments are being maintained at a normal rate, sinking, raising, and drifting are being carried on in the Mayflower vein. The company is building a spur-track and ore-bins to facilitate the shipment of ore. The development work in the Mayflower vein has as its objective the opening of rich shoots of ore found in the Montana-Bingham level. The average of the shipments from these shoots during the past year had been 6 to 16% copper, 2 to 6 oz. silver, and from \$1.50 to \$4 in gold. In addition, the ore carries an excess of iron, which reduces the cost of smelting to a minimum. Sinking upon this vein has progressed 215 ft. below the Montana-Bingham level. A shipment from the 150-ft. sub-level recently made averaged 12% copper and 4 oz. silver per ton. Development of these shoots indicates that the enrichment is increasing as greater depth is attained.

EUREKA.—The directors of the Tintie Standard Mining Co. have declared a quarterly dividend of 10c. per share, aggregating \$117,470, payable July 20. This will bring the total dividend disbursements up to \$1,186,192. The ore-reserves in the mine are being increased and the property is in excellent shape. The main working shaft is at a depth of 1450 ft., and there is a large amount of good ore on that level, although no effort is being made to draw ore from that depth. Drifts are being sent into the ore for the purpose of determining the size and value of the deposit.

Because of the surplus of ore at its plants, the American Smelting & Refining Co. placed a temporary embargo against the shipment of ore from some of the Tintie mines. Iron ore, however, was accepted at full production. The embargo was lifted on June 20. The Eagle & Blue Bell and the Victoria were the hardest hit by this embargo, practically all of the product from those mines being sold to the A. S. & R. Co. Some of the other large shippers have contracts with the United States and International Smelting companies and were not seriously affected by the embargo. A total of 143 cars was shipped during the week ending June 12, of which the Chief Consolidated shipped 40; Tintie Standard, 20; Iron Blossom, 17; Dragon, 17; Grand Central, 8; Gemini, 7; Iron King, 6; Centennial-Eureka, 6; Eagle & Blue Bell, 4; Colorado, 3; Empire, 3; Victoria, 2; Godiva, 2; Seranton, 2; Cornucopia, 2; Mammoth, 2; Primrose, 1; Sunbeam, 1.

After several months of development work the Tintie Paymaster Mines Co., in the North Tintie district, has been rewarded by the disclosure of the first shipping ore opened at any considerable depth. On the 400-ft. level in the north drift, which was started from the main east drift when it cut a fissure about 400 ft. from the bottom of the shaft, a stringer of ore, varying from 8 to 18 inches in width and averaging \$7.65 in gold and 16 ounces of silver per ton, was found. H. G. Snyder, manager, also states that the east drift, now in 850 ft., is showing an important change in formation, indicating the nearness of one of the large objective fissures.

Leasing operations at the Centennial-Eureka mine are active. Recently a shipment made by Irwin Spriggs netted between \$4000 and \$5000 for one carload. At the Iron Blossom mine, sixty lessees are working. One shipment, taken from what is known as the Jackson-Swensen lease, averaged 180 oz. silver per ton, while shipments from this same mine, by other lessees, are averaging from 100 to 114 oz. silver per ton.

John Enlund superintendent of the local properties of the United States Smelting Co., states that the work of re-timbering the Bullion Beck shaft is going along quite rapidly. It is expected this work will be completed by July 5, when hoisting operations will be resumed. Since the shaft work was started, the lessees in the Bullion Beck have been using the workings of the Gemini and Centennial Eureka in going to and from work, while the ore has been stored in underground workings.

PAK CITY.—The Judge Mining & Smelting Co. has posted dividend No. 37, being the regular quarterly dis-

dividend of 12½¢ per share. This will total \$600,000 and will be paid on July 1. The grand total of dividend disbursements to date by this company is \$3,380,000. The electrolytic smelter of the Judge company is operating in a satisfactory way, according to G. W. Lambourne, general manager. One-half of the plant is producing its rated capacity of seven tons of zinc cathodes per day. Physical conditions in the mine are most promising.

The Naildriver mine is looking better than ever in its history, according to company officials. In the cross cut on the 700-ft. level, there is three feet of good ore in the face; on the 600-ft. level the entire face is in ore; and on the 500-ft. level, there is from two to four feet of ore.

Labor is becoming more plentiful, and with continually improving conditions in the King Coalition, the Ontario, the Keystone, the Naildriver, and the Park-Utah mines, the outlook in the district is brighter than at any time in years. Shipments for the week ending June 12 totalled 2004 tons, as against 1817 tons for the preceding week. The Judge M. & S. shipped 812 tons of ore and the smelter 35 tons of spelter; the Ontario, 504 tons; the Silver King Coalition, 441 tons, and the Daly-West, 224 tons.

The directors of the Daly Mining Co. have declared a dividend of 10¢ per share, payable July 2. This is the ninety-third dividend to be paid by this company, and it will call for a total of \$15,000. The company is controlled by Col. E. A. Wall, who recently gave an option on all of his holdings to Geo. W. Lambourne of the Daly-West company, at a price of approximately \$3 per share.

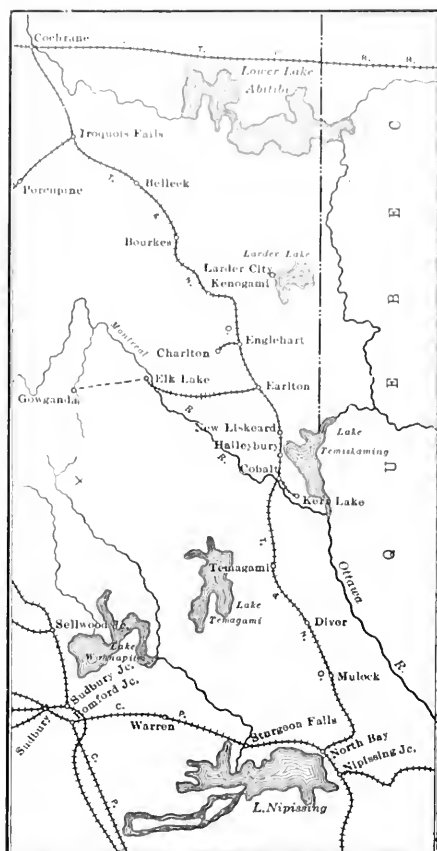

ALTA.—With the Little Cottonwood railroad opened to its terminus, mining men are looking forward to the most productive season in years. Shipments are now being made down the three canyons steadily. The largest shippers this season will be the Cardiff, the Sells, the South Hecla, the Columbus Rexall, the Emma Silver, the Michigan-Utah, the Alta Consolidated, and the Louise. The South Hecla mine, according to George H. Watson, general manager, during the past month has opened a rich stope in the east side of the property, known as the 'Rustler'. The carbonate stope, which has been placed in readiness for production on the 600-ft. level on the west side of the mine, shows a better grade of direct smelting ore than on any of the levels above. These stopes are almost 4000 ft. apart, showing that the mineralization in the property is persistent. There are excellent prospects of other stopes being opened between those now ready for production.

BRITISH COLUMBIA

DOLLY VARDEN RAILWAY IS OPERATING.

ALICE ARM.—The Alice Arm-Dolly Varden railway is in operation and the mine is making regular shipments to Anyox, once again. The work of erecting new ore-bunkers is well under way, and soon they will be in use and will considerably facilitate shipping. The railway is being re-railled with 50-lb. rails in place of the 35-lb. rails that originally were laid. There has been a big influx of people to Alice Arm, many of whom are living in tents, as

there is no other accommodation. Three hotels are in course of construction. The Goltschish mine, at Silverter bay has made a number of small shipments to Anyox, recently. The vein has an average width of six feet, and has been uncovered on the surface over a length of nearly 3000 ft. The ore runs high in both gold and silver, some samples assaying upward of \$3000 per ton, and it is in demand at the smelter for fluxing purposes. A wharf is being built and a tunnel is being driven to cut the vein

MAP OF NORTHERN ONTARIO

at a lower level. When this is completed the ore will be trammed from the tunnel directly to the wharf and shipped in scows to Anyox, three miles away. A three-drill compressor is being erected at the property. Work has been started at the Patricia group, four miles up the south fork of the Marmot river. A four-foot vein assaying \$15 to \$25 in gold and 50 to 60 oz. in silver is being developed.

TRAIL.—After giving it a thorough test, lasting over several months, the Consolidated M. & S. Co. has decided to abandon the idea of a wet magnetic concentration in favor of flotation for its Sullivan mine ore. The ex-

portamental plant failed, of course, to remove the pyrite which at times there is a considerable amount. The plant is being dismantled and another flotation plant will be erected in its place and on the same site. It is expected that the company will blow-in one of the copper blast furnaces and start part of the converter plant and part of the copper refinery about the beginning of July. The other blast-furnaces will be put in operation as the needs demand, which will depend largely on when the Canada Copper Corporation starts to produce concentrate. It is expected, too, that shipping of high-grade ore will be resumed shortly from the company's Rossland mines. It is unlikely that any quantity of low-grade ore will be shipped until the concentrating plant, which is being erected to treat this ore at Trail, is completed. Only development work has been done at the Rossland mines for several months, and the miners will welcome the starting of mining operations again.

GREENWOOD.—Duncan McIntosh, one of the lessees of the Bell mine, reports that the mine work is continuing as actively as the shortage of labor will permit. However, the men available are working in ore averaging 175 oz. silver, 8% lead, and about 8% zinc. Nearly 1100 ft. of driving and cross-cutting has been done and several good veins are exposed, three of which are being worked.

QUESNEL.—The operations of S. J. Marsh, of the Cariboo Gold Platinum Extracting Co., are being watched with interest by the miners of the Cariboo, as well as by those interested in placer ground throughout the Province. Mr. Marsh announces that he is in the market for black sand such as is found along the Fraser, Tulameen, Thompson, and other rivers of British Columbia. This contains some gold and platinum and it is Mr. Marsh's claim that he has invented, and demonstrated in a practical way, a device for the economic extraction of these precious metals from the sand. The plant necessary for his "electro-chemical process," as it is termed, is reported to have been assembled at Quesnel. Mr. Marsh, in his request for black sand of the character indicated, undertakes to guarantee a recovery of 90% of the assay value of the same. In order to assure the continuous operation of the Quesnel plant he is installing on the Quesnel river, some 28 miles above the town, a drag-seine dredge equipped with a concentrating device designed to separate the black sand from the gravel.

ONTARIO

PRODUCTION OF COBALT HELPS SILVER-MINING COMPANIES

COBALT.—During the first quarter of 1920, the mines of Ontario produced \$2,954,695 worth of silver, as compared with \$3,152,700 during the corresponding period of 1919. This decline of \$198,005 was more than offset, however, by an increase of \$233,000 in the value of cobalt and cobalt oxide produced as a by-product from the silver mines. Inclusive of the by-product, the value of the output for the first quarter of 1920 amounted to \$3,404,774, as compared with \$3,369,152 for the corresponding period of 1919.

During May the Nipissing mine produced \$335,597,

making a total of \$1,837,118 for the first five months of the current year. The low-grade mill treated 7138 tons and the high-grade plant 196 tons of ore. Several new veins, very narrow but of comparatively high grade, were opened during the month.

Arrangements are being made to re-open the Colonial mine. This property has been idle for a number of years. It is situated adjacent to the O'Brien mine as well as the Violet property of the La Rose Consolidated. It is in the hands of strong American financial interests who are fully conscious of the fact that the property has potentialities and who refused repeated offers for its purchase. Underground work is now being laid out.

PORCUPINE.—The Davidson is arranging for operations on a largely increased scale. The workings are now at a depth of 600 ft. with a good tonnage of ore opened at various levels. Sections of the drift on the 500-ft. level are stated to show an average gold content of \$49.20 over a considerable distance. Diamond-drilling is being carried on to explore the vein at a depth of 1500 ft. and a new four-compartment shaft will be sunk to the 1000-ft. level. The Keora-Porcupine has struck a new vein of good ore eight feet wide in sinking its new shaft at a depth of 160 ft. The Hudson Bay Mines has discontinued operations at the Dome Lake and the mine is now flooded with water.

KIRKLAND LAKE.—The opening of the Tough-Oakes mine has been considerably delayed and no underground work has yet been undertaken. The mill is being repaired and will shortly be in good condition. The Kalgoolie-Kirkland Gold Mines, Ltd., organized in December last, has gone into liquidation.

BOSTON CREEK.—This camp narrowly escaped destruction last week from the bush fires which ravaged large areas in Northern Ontario. It was entirely cut off from communication with the outside and the citizens fought the flames for three days before the danger was over. Work at the Miller Independence has been speeded up since the installation of electric equipment. At the 500-ft. level the cross-cut, which is being run to cut the vein, is now 200 ft. from the shaft, and is passing stringers carrying sulphides, indicating the proximity of the vein.

GOWANDA.—Activity in this field is being stimulated by the prospect of the improvement of transportation conditions by the building of the railway from Elk Lake. The operating companies have not been handicapped by labor shortage so badly as in other mining districts. The shaft on the Castle property of the Trethewey is down over 150 ft., at which depth the vein shows a width of six inches of high-grade ore in addition to several feet of milling material. Thirty tons of high-grade is ready for shipment. On the Bonsall, adjoining the Castle, high-grade ore has been found at the 100-ft. level. The Reeves-Dobie is preparing to begin operations, and a number of small properties will be worked on a larger scale as soon as the high cost of supplies and material is reduced by the construction of the railway. The Big Four mining plant was completely destroyed by a forest-fire and other properties were in considerable danger.

PERSONAL

The Editor invites members of the profession to send particulars of their work and appointments. The information is interesting to our readers.

Weldon J. Crook is in Seattle.

W. W. Mohr is at Lake Tahoe.

George B. Terrell is at Long Lake, New York.

H. H. Palmer, of Boise, Idaho, is in San Francisco.

W. T. Jones, of Ranger, Texas, is at Salt Lake City.

Morton Webber has returned from Idaho to New York.

J. Burns Read, of Urbana, Illinois, is at Golden, Colorado.

Jeffrey Schweitzer, of Tonopah, Nevada, is in San Francisco.

James Martin, of Yucca, Arizona, is at San Diego, California.

H. H. Schlapp is expected shortly in San Francisco from Melbourne.

Albert Turner has gone from Oatman, Arizona, to London, England.

Herbert A. Wilcox, of Pasadena, California, has moved to Aspen, Colorado.

Fernando Montijo Jr., of Arizpe, Mexico, is at Berkeley for a short time.

E. A. Strong, formerly of Ocotello, Arizona, is at Mokelumne Hill, California.

E. P. Mathewson, of New York, made a brief visit to the Globe district recently.

T. A. Rickard gave an address before the Los Angeles section of the Institute on June 25.

Thomas H. Teal is manager for the Liberty Mining & Reduction Co., at Montezuma, Colorado.

R. H. Channing, president of the Utah Con. Mining Co., at Bingham, Utah, is at Salt Lake City.

W. L. Kerr, of Denver, is at Los Angeles, on his way to examine a mine in southern California.

W. W. Copp, of Nelson, Nevada, is now with the United Eastern Mining Co., at Oatman, Arizona.

Horace G. Nichols is general mine-superintendent for the Mazapil Copper Co., in Zacatecas, Mexico.

A. C. Ensign has been appointed assistant superintendent of the Arthur plant for the Utah Copper Co.

Richard M. Geppert, of Minneapolis, is on his way to make an examination of mines in British Columbia.

John Kiddie, division-superintendent of the Arizona Copper Co., is spending a few weeks in California.

H. C. Goodrich, chief engineer for the Utah Copper Co., was at Los Angeles and San Francisco recently.

J. N. Hauser, general manager for the Tennessee Copper Co., is making a trip to Western mining camps.

Morris P. Kirk has resigned as general manager for the Yellow Pine Mining Co., at Good Springs, Nevada.

Sidney J. Kidder, general manager for the Mogollon Mines Co., New Mexico, was a recent visitor to the Clifton-Morenci district.

J. M. Hill is the geologist assigned to the San Francisco office of the Geological Survey. He will begin work here on August 1.

Frank P. Knight, president of the Iron Cap Copper Co., who has been spending the winter at Globe, has returned to his home at Boston.

Paul Lord, formerly general foreman of the Morenci branch of the Phelps Dodge Corporation, has been promoted to mine-superintendent.

E. W. Engelmann, research engineer for the Jackling porphyry properties, is making an inspection of the Ray and Chino concentrating plants.

George H. Garrey, consulting geologist for the Tonopah

Belmont Development Co., has just returned from a trip to Surf Inlet, British Columbia.

George P. James, formerly mine foreman with the South American Development Co., at Ecuador, is now with the Guggenheim Brothers, at La Paz, Bolivia.

Charles E. Sturtevant, mining engineer of Salt Lake City, has returned from Bolivia, where he examined the Empressa Trinaeria property for New York capitalists.

C. H. Benedict, chief metallurgist for the Calumet & Hecla company, is in attendance at the National Convention of the Democrats as one of the delegates from Michigan.

R. O. Dobbs, manager for the Louise Mining Co. at Alta, Utah, is making an examination of the Silver Slipper mine in the Silver district, 18 miles north of Wendover, Utah.

George Kingston, general manager for the United Verde Extension Mining Co., and Dave Morgan, manager for the Verde Combination Copper Co., sailed for Europe recently.

I. Cummings, for many years smelter-foreman for the Cananea Con. Copper Co., has gone to Venezuela where he will enter the service of a South American copper company.

Ernest Gayford, of the General Engineering Co., Salt Lake City, has been making an inspection of the property of the Stargo Mines Co., preliminary to the construction of a mill.

John Linn, mine superintendent for the Empire Copper Co., has resigned. He has been succeeded by L. D. Abels, formerly of the Santa Gertrudis and Peñoles mines in Mexico.

James Colquhoun, for many years general manager for the Arizona Copper Co., has been spending several weeks in the Clifton-Morenci district with his son Capt. Clifton Colquhoun.

John C. Greenway, general manager for the Calumet & Arizona and New Cornelia Copper companies, recently made the trip from Ajo to Tucson, a distance of 115 miles, by aeroplane in one hour and fifteen minutes.

T. H. Jenks, of Los Angeles, who has been spending some time in New York and Boston, is now on his way to Denver and will be engaged upon professional work in Colorado most of the summer with headquarters at Lake City.

Frank Pelton, mine-superintendent of the Tyrone branch of the Phelps Dodge Corporation, has resigned and expects to engage in business in New York. Donald Miller, formerly assistant superintendent, has been appointed mine-superintendent.

Obituary

Whitfield P. Pressinger, vice-president of the Chicago Pneumatic Tool Co., died in New York on June 10 as a result of complications following an operation. He was actively engaged in the pneumatic tool and allied machinery industry for many years. He was general manager for the Clayton Air Compressor Co. for seven years and became widely known through activities in the American Society of Mechanical Engineers and the Compressed Air Society. He was born in New York City in 1871.

Frank C. Garbutt died on June 13 at his home in Los Angeles. He was born near Toronto, Canada, in 1837, but came to the United States when 16 years old. He worked his way through Harvard, and served with the Union Army during the Civil War. In 1871 he went to Colorado where he practised his profession as a mining engineer. He erected a number of metallurgical plants including the reduction works at Salina; the Wyndam smelter, near Ouray; the Elgin smelter at Leadville; and the Redcliff plant at Battle Mountain. The Garbutt mine is credited with the production of several millions. At the age of 80 he was still engaged actively in mining ventures in the South-West and in Mexico. He was a prominent and respected figure in the business and social life of Los Angeles.

THE MINING SUMMARY

ARIZONA

Globe. The mill of the Iron Cap Copper Co. started on the morning of June 8. While it is now running half capacity the remaining unit will be put in operation shortly.

Inspiration will commence to sink two winzes from the 600-ft. level to the bottom of the orebodies for the purpose of exploring the lower levels of the ore, and also to open up a deeper haulage-level.

Humboldt.—The De Sota and Blue Bell mines of the Consolidated Arizona Smelting Co. shipped to the mills and smelter during the month of May 11,600 tons of ore. Of this tonnage the concentrator handled 7700 tons and the smelter treated 9000 tons. There was shipped to the refineries 1,250,000 lb. of copper, a little less than half of which was from company ores. The mill and smelter handled considerably more ore than during the past several months.

Jerome.—The Jerome Superior Copper Co. is to change its present oil-burning equipment for electrical machinery. The shaft, which is at present 840 ft. deep, is to be sunk to the 1500-ft. level. Pumps will be installed at the 1000 and 1500-ft. levels. The diamond-drilling which was being done on the 700-ft. level has been discontinued because of difficulties due to fractured ground. A splendid showing of shipping ore has been opened by a shallow shaft on the Jerome Central. Arrangements are under way for the financing of the Jerome Central. This property is south of the Smith group and the adjoining Black Hills patented claims $1\frac{1}{2}$ miles south of Jerome.

CALIFORNIA

Nevada County.—Considerable interest attaches to the finding of high-grade silver ore in the Alcalde mine. The silver is found in a small shoot, accompanied by gold, and marks a rare occurrence in the Grass Valley district. Development of the main gold vein continues satisfactory, and the product going to the mill is said to be netting substantial profits.

Placer County.—The Nevada Pacific Exploration Co. has completed a test-run of its new 60-ton mill near Forest Hill and will make the initial clean-up before the end of June. The mill is stated to be operating satisfactorily and is apparently a success in all ways. Two prominent veins have been opened and sufficient ore is in sight to ensure steady production for two years. The company is also developing the Josephine group, in El Dorado county. The lower cross-cut has entered a small shoot of ore about 100 ft. in advance of the point where the vein was anticipated. The Josephine is credited with an output of \$550,000 from the old workings.

San Benito County.—The main plant of the New Idria Quicksilver Mining Co. was destroyed by fire on June 20. This company is the largest producer of quicksilver in the United States and probably in the world. Approximately 250 men will be out of work pending the reconstruction. Defective wiring is assigned as the cause of the fire. A large oil-tank was ignited and exploded, flooding the tramway terminal with the blazing fluid. The ore-crushing plant, warehouse, blacksmith-shop, furnaces, and several miners'

cabins also were destroyed. The loss is estimated at more than \$100,000.

Shasta County.—Preliminary work has begun at the Bully Hill mines, in which D. C. Jackling and associates have recently acquired an interest. Tunnels and shafts are being cleared, improvements made to the railroad, and the old smelter-site cleaned up. The site for the new \$1,000,000 smelter has been chosen across the ravine from the present smelter and north of the old plant. It is understood at Redding that within ninety days several hundred men will be put to work on the building and development planned. The group of claims has been developed to an approximate depth of 1000 ft. and is one of the richest copper-zinc mines in California.

Tuolumne County.—Seventy stamps are dropping at the Shawmut mill, and concentrate is being converted into bullion at the new refinery. The mine is working with a full crew and little difficulty has been experienced by the management in retaining its labor. This is said to be due to the excellent living accommodations provided by the company. Ore developments on the deeper levels continues satisfactory. The Shawmut is controlled by the Belmont Development Co. of Tonopah, and ranks high among the foremost producers on the Mother Lode.

COLORADO

Saguache County.—The Utah Leasing Co., a subsidiary of the Western Metals Co. of Salt Lake City, has taken over the Rawley properties near Bonanza, and will operate mines on a considerable scale. A 700-ton concentrator erected at Midvale, Utah, is being dismantled and shipped to Shirley, where it will be connected with the mines by a 7-mile tramway. The mines are developed by a 6000-ft. tunnel with a 1200-ft. raise to the surface and with numerous levels and drifts, which disclose large bodies of silver, gold, and copper ore. It is estimated that upward of \$250,000 will be spent in construction, equipment, and development and that the greater part of the year will be required to place the plant in operation.

IDAHO

Bonner County.—Re-opening of gold claims near Hope is being undertaken by the Auxer Gold Mines Co. of Hope, recently incorporated with a capitalization of \$500,000. It will work seven gold and silver claims. Considerable work has been done in the mine in recent years, including a 250-ft. tunnel and a 90-ft. shaft, with three drifts and several crosscuts. Work is expected to start by July 1.

Coeur d'Alene.—The Cedar Creek Mining & Development Co. is advancing a drift on a vein found some time ago. The orebody is 26 ft. wide. Exploratory work done recently about 150 ft. from the face is reported to have revealed ore 35 ft. wide.

The Majestic Mining Co., whose mine is $1\frac{1}{2}$ miles north-east of Burke, is starting a tunnel to cut at great depth the two veins opened on the main tunnel level. A winze will be sunk for a short distance on the vein in the main tunnel.

The Giant Ledge Mining Co. has opened ore for a long distance on the 400-ft. level of its main-shaft workings and men have been sent to the property to continue construction of the mill. Ore has been followed for 1400 feet.

THE METAL MARKET

METAL PRICES

San Francisco, June 22

Aluminum dust, cents per pound	65
Antimony, cents per pound	10
Copper, electrolytic, cents per pound	19
Lead, pig, cents per pound	8.25-9.25

Zinc dust, cents per pound	12.50-15.00

EASTERN METAL MARKET

(By wire from New York)

June 21—Copper is inactive but steady. Lead is quiet and lower. Zinc is dull and easier.

SILVER

Below are given official or ticker quotations, in cents per ounce of silver 999 fine. From April 23, 1918, the United States government paid \$1 per ounce for all silver purchased by it, fixing a maximum of \$1.01 1/2 on August 15, 1918, and will continue to pay \$1 until the quantity specified under the Act is purchased, probably extending over several years. On May 5, 1919, all restrictions on the metal were removed, resulting in fluctuations. During the restricted period, the British government fixed the maximum price five times, the last being on March 25, 1919, on account of the low rate of sterling exchange, but removed all restrictions on May 10. The equivalent of dollar silver (1000 fine) in British currency is 46.65 pence per ounce (925 fine) calculated at the normal rate of exchange.

FRENCH TO BUY COPPER IN UNITED STATES

It is reported that French consumers have contracted to purchase 75,000 tons or 108,000,000 lb. of copper. This is the largest individual sale for export since 1918, and involves approximately \$32,000,000, based on present market price. The Copper Export Association will handle the business for American producers. French consumers will take approximately 3000 tons or 6,720,000 lb. monthly for two years to come. A new contract calls for payment of current market price at the time of shipment. Buyers are given 90-day credits, with option of exercising three 90-day renewals. In other words, French consumers have a year from the time of shipment in which to pay for the copper. Copper authorities expect that other foreign consumers will enter the market now that French buyers have contracted to take this big block of metal, and it is predicted the price of copper will advance steadily due to the fact that producers are curtailing output due to labor shortage and poor transportation facilities. The existing dullness in the domestic market is accounted for by the heavy buying in March, which met the requirements of consumers for some time in advance.

THE SILVER MARKET ABROAD

Samuel Montagu & Co. in a recent market letter, says:

"The rally last week in exchange in China proved to be put temporary; support from that quarter has only been at falling rates and even then somewhat reluctant in character. As India is still refraining from purchases, the market does not possess much animation—a state of affairs not improved by sales from America, where the quotation has dipped below one dollar per ounce. Even if fresh American-produced supplies (say 60,000,000 oz. per annum) are absorbed by the U. S. Mint, the outlook for silver is not good, for melted coin for realization is arriving and likely to arrive from the Continent in substantial quantities; that is to say, the Continent, which was a continual buyer of considerable amounts before the War, is now a seller on balance to a very appreciable extent. The drastic requirements of the U. S. Mint for coin before the War, though actually suitable, to be excluded from purchase because the owners cannot definitely verify the contents.

In view of the great absorption of silver in India and the small production in that country (even by the Director of the U. S. Mint as 270,000 oz. in 1918), the recent discovery of a silver lode near the Tata Iron & Steel Co.'s works in Bengal is of interest. The vein is seven feet thick and has been uncovered to a length of 1000 ft. and a depth of 70 ft. The assay averages 600 oz. of silver per ton (together with some gold). The first bars from the mine were expected in Calcutta at the end of last month. The Times of India states that the presence of silver and gold in the transition rocks of South Bihar and Bengal has long been recognized, but hitherto these metals have not been found in this region in remunerative quantities.

MONEY AND EXCHANGE

Foreign quotations on June 22 are as follows:

Sterling, dollars: Cable	4.00
" Demand	4.75
France, cents: Cable	8.40
" Demand	8.43
Lire, cents: Demand	6.28
Mark, cents: Demand	2.85

Eastern Metal Market

New York, June 16.

All the markets are quite generally inactive and show few signs of an early resumption of buying.

Demand for copper is very light but producers' prices are

The tin market is declining and consumers are disinclined to enter.

An easier tendency in lead is apparent and there is no disposition to buy.

There is no change in demand or prices for zinc. Both are fairly steady.

Antimony is lower because of the decline in silver.

IRON AND STEEL

Steel production keeps up at a higher rate than the very moderate betterment in car-movement would indicate. It is to be expected that the gorge of finished material at various mills will be broken as the railroads keep working on it, but for many weeks coal and coke supply will be the key to the whole iron and steel situation. In the past week hot weather and the breaking-in of so many new railroad workers have shown that a trying summer is ahead.

The May output of steel ingots, partly estimated, was about 3,430,000 tons, a gain of 10% over April, and the industry was surprised that the total for the past five months was at a yearly rate of 41,400,000 tons, pointing to the possibility that 1920 may yet be one of the three great years in steel. Consumers who are wrestling with the most difficult situation in all their experience are still puzzled by the large production and the smallness of the visible supply of finished steel of nearly all descriptions.

COPPER

A diagnosis of the present situation in copper based on the opinion of a representative of a leading producer is about as follows: The heavy buying in March covered the needs of most consumers through June and in some cases into July. In April and May the railroad and labor troubles interfered decidedly with consumption, shipment, and also with production, thus pushing ahead supplies ultimately expected to be consumed by the end of June. The buying-movement which normally would have been expected this month has therefore been put forward two or more months. Also there is no cause for active purchasing now by large consumers at least. The market is therefore quite inactive and devoid of interest. Leading producers, however, continue to maintain their prices firmly at 19c., New York, for June-July delivery and see no reason to change them. From dealers and other sources some small lots are obtainable at anywhere from 18.25 to 18.75c., New York.

TIN

This market has fallen to new low levels on this movement, spot Straits having touched 46.50c., New York, on June 16 and 14, and 45.50c. yesterday. The market has been quiet and dull with consumers, while showing some interest, apparently afraid to make purchases and discouraged because of the general industrial situation. They appear to have, however, supplies for several months longer. On Monday, June 14, quotations were largely nominal with all positions ruling at 46.50c., London having been higher on that day, but New York lower, due to the decline in silver. Yesterday there was a further slump in London with spot Straits quoted at £260 per ton, a decline of £20 per ton since a week ago. The New York spot Straits quotation yesterday was also lower, 45.50c. Sales during the week were light, aggregating not over 300 tons at price-ranges of 46.25c. to

48.37½c. for future shipments. Chinese No. 1 tin sold at 43c. for April, May, and June shipment. Arrivals thus far this month have been 1915 tons with the quantity afloat at 4645 tons.

LEAD

Consumers are entirely indifferent and do not desire to buy. There is now no difficulty in buying spot lead, New York, at 9c. and it can be had under this level or at about 8.87½c., although it is not generally so offered. Lead in transit is also obtainable at 8.87½c., New York. The movement of the metal is much freer but consumers have no faith in present prices. As a result the market is dull, stale, and stagnant. One interest yesterday expressed the opinion that lead might fall to 7c. in the next two or three months. For delivery in 30 days we quote the market unchanged at 8.50c., St. Louis, or 8.75c., New York.

ZINC

This market continues in its lifeless condition. Under the circumstances prices are fairly steady. Prime Western is quoted at 7.55c., St. Louis, or 7.90c., New York, for delivery into the third quarter, but little buying is reported. Large producers are supplying only the needs of regular customers at prevailing quotations which are made largely by dealers and traders. One prediction is that zinc will fall to 7c., St. Louis, before the trend reverses and it goes higher.

ANTIMONY

The recent decline of many points in silver has affected this market which is lower at 7.75c., New York, duty paid, for wholesale lots for early delivery.

ALUMINUM

Wholesale lots of virgin metal, 98 to 99% pure, for early delivery are quoted at 33c., New York, by the leading interest and at 31.50c. by other sellers.

ORES

Tungsten: The market is still inactive with no trend one way or the other. Prices are nominal.

Ferro-tungsten is unchanged at 85c. to \$1.15 per lb. of contained tungsten.

Molybdenum: This market is also featureless and dead with quotations nominal at 75c. per lb. of MoS₂ in regular concentrate.

Manganese: Prices are firm at 80c. to \$1 per unit but offerings are light. Demand is excellent and sales could easily be made because the number of producers of ferro-manganese is increasing, both blast-furnace and electric furnace. Recent transactions indicate that the imports of Indian manganese ore to this country will increase considerably in the second half of the year. The first manganese ore from the Caucasus since 1914 recently reached England at a price close to £12 per ton.

Manganese-Iron Alloys: There is a surprising lack of inquiry for ferro-manganese for either spot or last-half deliveries. If consumers are waiting for lower prices they are likely to be disappointed in the opinion of many in the trade. Prices are unchanged at \$225 to \$250, delivered, for June and \$200 for last half. Production in May was 22,663 gross tons, according to revised statistics of "The Iron Age". This is the largest output for any month this year, the April production having been 21,028 tons. The spiegeleisen market is quiet and strong at \$75. furnace, with only small lots reported sold. The output in May was 10,744 tons, which compares with 15,172 tons in March.

INDUSTRIAL PROGRESS

INFORMATION FURNISHED BY MANUFACTURERS

THE USE OF WOOD PIPE

Wood pipe is recommended for a wide variety of purposes under greatly varying conditions. There are, however, certain restrictions placed on its use which are recognized by the wood-pipe manufacturers. They are making a strenuous effort to encourage the use of their products in those instances where its suitability has been demonstrated and just as strenuous an effort to discourage its use for those purposes and under those conditions where its unsuitability has been proved. The reason that they take this position is obvious—the greatest development of any industry depends primarily on the intelligent use of the product manu-

lished by the U. S. Department of Agriculture and reported in Bulletin No. 376 by Fred C. Scooby. In 1916, Mr. Scooby made a series of sixty-four tests in sixteen separate pipe lines, and from the results of these tests, together with the reports of many prominent investigators on this subject, has published a formula for the flow of water in wood pipe and also tables showing the capacity of different sizes of pipe. As a result of Mr. Scooby's investigations, his conclusion is, "that wood pipe will convey about 15% more water than a 10-year old cast-iron pipe or a new riveted pipe, and about 25% more than a cast-iron pipe 20 years old or a riveted pipe 10 years old".

While low cost and high efficiency and greater capacity are often determining factors, adaptability many times has led to the use of wood pipe regardless of other factors. A large proportion of the existing water-supply pipe-lines in use today traverse remote and inaccessible districts. The transportation of materials of construction to the line of work and the assembling of same into a complete pipe-line has proved a problem most easily solved by the use of wood pipe. The smaller sizes of wood pipe are easily transported, being light in weight and of convenient length. The larger sizes of wood pipe are shipped in the 'knocked down' and assembled in place into a complete pipe-line. The length of staves and number of bands or

Twelve-Foot Wood Pipe-Line at Trenton Falls, N. Y.

factured. With this idea in mind the advantages of wood pipe may be pointed out with exceptional clarity.

The primary purpose of a pipe-line is to deliver water or other liquids from one point to another, this operation to be continued for a certain length of time or more likely for an indefinitely long period. The low initial cost of wood pipe, the low maintenance cost, and the saving effected in interest charges by reason of low initial investment, make it the most economical pipe that can be installed regardless of the period of service required. The efficiency of any pipe-line is relative; that is, it may serve the purpose for which it is intended better or worse than a line constructed of other materials. Wood pipe, by reason of its smooth internal surface and its freedom from corrosion, tuberculation, or other action tending to reduce this original smoothness, is unquestionably the most efficient pipe yet produced.

Efficiency and capacity are so closely related that a reference to one naturally suggests the other. That under the same conditions, wood pipe will convey more water than the same diameter pipe made of other materials, which are at times considered as substitutes, has been definitely estab-

lished by the U. S. Department of Agriculture and reported in Bulletin No. 376 by Fred C. Scooby. In 1916, Mr. Scooby made a series of sixty-four tests in sixteen separate pipe lines, and from the results of these tests, together with the reports of many prominent investigators on this subject, has published a formula for the flow of water in wood pipe and also tables showing the capacity of different sizes of pipe. As a result of Mr. Scooby's investigations, his conclusion is, "that wood pipe will convey about 15% more water than a 10-year old cast-iron pipe or a new riveted pipe, and about 25% more than a cast-iron pipe 20 years old or a riveted pipe 10 years old".

While low cost and high efficiency and greater capacity are often determining factors, adaptability many times has led to the use of wood pipe regardless of other factors. A large proportion of the existing water-supply pipe-lines in use today traverse remote and inaccessible districts. The transportation of materials of construction to the line of work and the assembling of same into a complete pipe-line has proved a problem most easily solved by the use of wood pipe. The smaller sizes of wood pipe are easily transported, being light in weight and of convenient length. The larger sizes of wood pipe are shipped in the 'knocked down' and assembled in place into a complete pipe-line. The length of staves and number of bands or

shoes per bundle can be accommodated to the means of transportation without interfering with the work of assembling or without reducing the efficiency of the completed pipe. Pipe as large as 14 ft. inside diameter is constructed of staves measuring approximately 4 by 6 in. in cross-section and of any desired length up to 40 ft. Consequently the construction of the largest pipe required offers no insurmountable difficulties to the wood-pipe manufacturers' experts and their experienced crews. Under adaptability may be mentioned also the fact that wood pipe is admirably suited for the construction of pipe-lines traversing country of uneven contour. Bends or sharp curves, if required, can be 'built into the line' by the experienced crews. It is possible to construct readily continuous-stave wood pipe-lines, winding up and down hill or around a bend as required. It is not possible for any other material to lend itself so readily to the installation of pipe-lines of this sort without excessive construction and assembling costs. Wood pipe is manufactured in three different types: wire-wound, continuous stave, and bored. Each type is made especially to serve a specific demand. The accompanying photograph shows a 12-ft.

wood pipe-line at Trenton Falls, New York. Among the mining companies that have wood pipe-lines are: Utah Copper Co., Arthur, Utah; Chino Copper Co., Hurley, New Mexico; Alaska Gastineau Mining Co., Juneau, Alaska; Anaconda Copper Mining Co., Anaconda, Montana; Burro Mountain Copper Co., Tyrone, New Mexico; Cerro de Pasco Mining Co., Peru; Gebroeders Veth, Pandang, Sumatra, British Columbia Copper Co., Greenwood, B. C.; Caribou Mines Co., Soda Springs, Idaho; American Smelting & Refining Co., Garfield, Utah; Braden Copper Co., Chile; Morococha Mining Co., Peru; Placerville Gold Mining Co., Placerville, California; Nevada Consolidated Copper Co., McGill, Nevada; Ray Consolidated Copper Co., Hayden, Arizona; Phelps Dodge Co., Bisbee, Arizona; United Comstock Pumping Association, Virginia City, Nevada.

PULMORE PULLEY TREAD

Almost every user or operator of belt-driven machinery has experienced—sometimes more frequently than desirable—excessive belt-slip or unusual wear due to a greater loading than that for which either the belt or pulleys were intended. Sometimes the loading may be due to a need for greater production beyond anything the belt or pulleys were designed and built to deliver—or to a lack of definite knowledge at the start just what the loading would be. There are various temporary or inadequate and harmful remedies for these conditions, such as excessive belt tension to eliminate slip, but with the resultant shorter life of the belt; or belt-dressings which may materially reduce the length of service a good belt should give.

Two permanent cures for excessive slip or overloading are larger pulleys and belts, or a pulley having friction surface equal to that of the belt. Pulmore pulley tread is a chemically treated fibre compressed into sheet form and it is easily applied to any kind of pulley simply by soaking in water for a few seconds to loosen up the chemical compound. When dry, it sticks to the pulley face and gives it a frictional tread equivalent to leather. Pulmore pulley tread gives this greater capacity equally well when used to cover iron, steel, wood, paper, or other pulleys used in connection with leather or other comparatively smooth-surfaced belts.

The difference in tractive friction is very apparent and is easily observed by one's sense of feeling in the case of an iron pulley, most of which is covered with the tread. In operation the uncovered part becomes polished and 'slippery' due to the constant creep or slip of the belt on the iron, while the treaded part presents a much more resistant surface alike to one's hand or fingers and to the belt. These then are the uses for Pulmore pulley tread:

1. By increased tractive friction obtained, to increase production with the same pulleys and belt.
2. To decrease belt-tension so that belts will last longer even when the same or greater power is transmitted.
3. To reduce frictional losses in bearings caused by excessive belt tension.
4. To lower first cost of pulleys, belts, and shafting by using smaller sizes.
5. To build up the crowning of worn pulleys or others needing a greater crown.
6. To eliminate troubles due to belts coming off because of excessive slip.

Bulletin No. 201, issued by Smith & Serrell, Newark, New Jersey, gives details of the merits, and directions for using Pulmore pulley tread.

The American Manganese Steel Co. announces that Walter Brinton, who was manager of its plant at New Castle, Delaware, for several years, has been elected vice-president of the company.

COMMERCIAL PARAGRAPHS

The Ingersoll-Rand Co. and the A. S. Cameron Steam Pump Works announce a change in their Chicago address. The new offices will be situated at 709 Fisher Building.

Girard B. Rosenblatt, electrical engineer specializing in the mining and metallurgical field, with the Westinghouse Electric & Manufacturing Co., has moved his office to 521 First National Bank Bldg., San Francisco.

The Worthington Pump & Machinery Corporation has issued an interesting announcement of its success in making a new Worthington marine oil-engine of 2400 indicated horse-power. The present engine is of Diesel type, has six cylinders, 29-in. bore, 46-in. stroke, and a speed of 120 r.p.m. Other sizes are planned.

The Southwestern Engineering Co. reports the following movements of members of its staff: Max Kraut is at the Arizona Middlemarch mine near Pearce, Arizona; E. J. Atekison is doing consulting work at the Argonaut tailing mill near Jackson, California; and L. C. Penhoel is at Nevada City, California.

The Gandy Belting Co. announces the appointment of Fielder I. Schillinger Jr. to the position of general sales manager, succeeding Chas. H. Dankmeyer, resigned. The recently opened Chicago branch at 549 West Washington St. will be under the charge of H. Milton Michel, who comes from the New York branch. Robert Crane will be in charge of the New York branch at 36 Warren street.

Rosenburg & Co. of Los Angeles announces the opening of a new warehouse at Phoenix, Arizona. A lease has been taken for the large building at 420 East Jefferson St., and it is the intention of the company to display a large stock of machinery immediately. This is the third warehouse opened by Rosenberg & Co. Eighteen months ago a warehouse was established at Congress Junction, Arizona. The new warehouse at Phoenix which opened July 1 will carry a \$500,000 stock of mining and milling machinery and equipment and in addition will house a large quantity of electrical goods. The Allingham flotation machine manufactured by Rosenberg & Co. will also be represented at the new Phoenix warehouse.

The accompanying illustration shows a water-driven hoist specially built for the South American Development Co. of Portovelo, Ecuador, by the Wellman-Seaver-Morgan Co. of

Water-Driven Mine Hoist

Cleveland, Ohio. As neither electricity nor steam was available the hoist was made to be operated by a W-S-M water-turbine. The present drive consists of one reduction by bevel-gearing, one reduction by spur-gearing, and one by herringbone gears, the turbine running continuously in one direction. The hoist is fitted with dial-indicator, two brake-bands and bevel-gear clutches. A feature of the design is the sectional construction. The maximum cordilleran pack-load is 300 lb. and the entire machine was transported by mule-back from Santa Rosa to the mine.
